

Compendium

National Population Projections: 2014-based projections

National population projections provide an indication of the future size and age structure of the UK and its constituent countries based on a set of assumptions of future fertility, mortality and migration, including a number of variant projections based on alternative scenarios.

1 . Introduction

National population projections by age and sex are produced for the UK and constituent countries every 2 years. These sets of projections are based on a review of the underlying assumptions regarding fertility, mortality and migration.

The primary purpose of the projections is to provide an estimate of future population which is used as a common framework for national planning in a number of different fields. The main focus of the 2014-based projections is on the next 25 years up to 2039, though longer-term projections to 2114 are also produced. Population projections become increasingly uncertain the further they are carried forward and particularly so for smaller geographical areas and age-sex breakdowns. In addition to the principal (main) projections, variant projections are also available, based on alternative assumptions of future fertility, mortality and migration. For more information on how our projections meet users' needs along with information on their fitness for purpose, please see the [report on quality and methodology \(290.9 Kb Pdf\)](#) on our website.

The 2014-based projections replace the 2012-based projections published on 6 November 2013.

The projections were produced by the Office of National Statistics (ONS) on behalf of the National Statistician and the Registrars General of Scotland and Northern Ireland. The underlying assumptions were agreed in liaison with the devolved administrations – [Welsh Government](#), [National Records of Scotland \(NRS\)](#) and [Northern Ireland Statistics and Research Agency \(NISRA\)](#) – following consultation with main users of projections in each country and advice from an expert academic advisory panel.

We have been responsible for the production of the official national population projections for the UK and its constituent countries since 31 January 2006. Prior to this, the responsibility lay with the Government Actuary's Department (GAD).

This report contains background information for the 2014-based national population projections. Included are sections on:

- defining the base population
- the method of projections
- the availability of projections
- background on principal and variants projections
- summary of the long-term assumptions of future levels of fertility, mortality and migration
- changes to the state pension age
- national population projections expert advisory panel

2 . Base population

Definition

The projections are based on estimates of the resident population of the UK and its constituent countries at mid-2014. The population includes all usually resident persons, whatever their nationality. Members of HM Armed Forces in the UK are included, but members of HM Armed Forces and their families who are abroad are excluded. Members of foreign armed forces in the UK are included, with any accompanying dependants.

Base populations for individual countries

The projections for England and Wales are based on the [mid-2014 population estimates](#) that we published on 25 June 2015. The projections for Scotland are based on the mid-2014 population estimates published by NRS on 30 April 2015 and likewise the projections for Northern Ireland are based on the mid-2014 estimates published by NISRA on 4 June 2015. These estimates are based on the results from the 2011 Census.

In October 2015, National Records of Scotland (NRS) announced small errors in the mid-year population estimates for areas in Scotland. Whilst these errors do not affect the total population of Scotland, or other parts of the UK, they do have a small effect on the age and sex distribution of the population. The impact of these errors is much smaller than the uncertainty around the estimates due to sampling error from the Census. NRS will publish corrected MYEs in April 2016.

The 2014-based NPP are based on the original release of the Scottish MYE in April 2015 and thus do not reflect the correction to the MYE for Scotland used as the base population for the projection. The errors will also have a small effect on the projected age distribution of cross-border migration flows from Scotland to England and Wales. These effects are very small compared to other sources of uncertainty in the projections.

Table 1.1: Base population estimates for 2014-based projections

	Thousands
England	54,317
Wales	3,092
Scotland	5,348
Northern Ireland	1,840
United Kingdom	64,597

Estimates of the population aged 90 and over

Official mid-year population estimates produced by ONS, NRS and NISRA are prepared by individual age to the age of 89, with an upper age band for all those aged 90 and over. Estimates of the population aged 90 to 104 by single year of age and for the 105 and over age group are prepared using the Kannisto Thatcher survivor ratio method, with the results controlled to agree with the official estimates of all those aged 90 and over.

3 . Method of projection

The projections are made for successive years running from one mid-year to the next. For each age the starting population, taking into account net migration less the number of deaths, produces the number in the population, one year older, at the end of the year. To this has to be added survivors of those born during the year. Age is defined as completed years at the last birthday.

Migration is assumed to occur evenly throughout the year. For computing purposes, this is equivalent to assuming that half the migrants in a given year at a given age migrate at the beginning of the year and half at the end of the year. The number of net migrants to be added to obtain the population aged $x+1$ at the end of the projection year therefore consists of half of those migrating during the year at age x and half of those migrating during the year at age $x+1$.

The number of deaths in a year is obtained by adding half of the net inward migrants at each age to the number in the population at the beginning of the year and applying the mortality rate q_x . The mortality rates used in the projections represent the probabilities of death between one mid-year and the next, according to a person's age last birthday at the beginning of the period. The appropriate rate of "infant mortality", that is, the probability of a new-born child not surviving until the following mid-year is also given. This is about 85% of the full, first year of life infant mortality rate used in official statistics.

The number of births in the year is calculated by multiplying the average number of women at each single year of age during the year (taken as the mean of the populations at that age at the beginning and end of the year) by the fertility rate applicable to them during that year. The total number of births in a year is assumed to be divided between the sexes in the ratio of 105 males to 100 females, in line with recent experience. The number of infants aged 0 at the end of the year is calculated by taking the projected number of births, deducting the number of deaths found by applying the infant mortality rate and adding half the number of net migrants aged 0 last birthday.

The principal projections are computed for each of the constituent countries of the UK and the results are added together to produce projections for England and Wales, Great Britain and the UK.

The assumptions have been set using rates based on a consistent series of population estimates which reflects the results of the 2011 Census.

4 . Available projections

For the 2014-based projections, principal projections data have been published up to 100 years ahead for the UK, Great Britain, England and Wales and each of the constituent countries.

Variant projections have been published up to 25 years ahead for the UK and each of the constituent countries. The low migration, high migration and zero net migration (natural change only) variants have also been published for Great Britain.

Data for each country or variant combination have been published in 2 summary tables and 1 zipped open data file.

Summary table 1 contains the total projected population for all years of the projections, the components of change and other summary statistics.

Summary table 2 contains the projected population in 5 year age groups for all years of the projection.

The XML open data files contain:

- population by single year of age (0 to 104), age groups (105 to 109, 110 and over) and sex
- fertility assumptions by single year of age (15 to 46)
- mortality assumptions by single year of age (0 to 125) and sex
- cross border rates for each country flow by single year of age (0 to 125) and sex
- births by age of mother (15 to 46)
- deaths by age (0 to 105 and over) and sex
- in, out and net cross border migration by age (0 to 105 and over) and sex
- in, out and net international migration by age (0 to 105 and over) and sex
- in, out and net total migration by single year of age (0 to 105 and over) and sex

The long-term figures should be treated with great caution. Population projections become increasingly uncertain the further they are carried forward and particularly so for smaller geographic areas and age-sex breakdowns.

Variant projections beyond the published 25 years and for alternative national geographic levels are available on request.

5 . Principal and variant projections

Background

The principal population projections provide a consistent starting point for all government planning which is affected by the numbers in the population. They are based on assumptions considered to be the best that could be made at the time they are adopted. However, due to the inherent uncertainty of demographic behaviour, any set of projections will inevitably be proved wrong, to a greater or lesser extent, as a forecast of future demographic events or population structure. To give users of the projections an indication of this uncertainty and to explore alternative scenarios, a number of variant population projections have also been produced, based on alternative assumptions of future fertility, mortality and migration.

Variants available from the 2014-based projections

In addition to the principal assumptions, high and low variant assumptions have been prepared for each of the 3 components of demographic change: fertility, life expectancy and migration. These variant assumptions are intended as plausible alternatives to the principal assumptions and do not represent upper or lower limits for future demographic behaviour.

Aside from the principal projection, 9 standard variant projections are presented here. These are the 6 possible "single component" variants (that is, varying only 1 component at a time from the principal assumptions); 2 'combination' variants: those produce the largest or smallest total population size, and 1 special case scenario of zero net migration (also known as natural change only). Seven further variant projections will be released on 26 November 2015, see Tables 1.2 and 1.3.

The variants allow users to explore a range of different possible future demographic situations. For example, the high and low migration variants for the UK provide alternative plausible scenarios for long-term net international migration at 80,000 above and below the principal net migration assumption, respectively. The low variant therefore assumes net migration of 105,000 per year, while the high variant assumes net migration of 265,000 per year.

In addition to high and low variants for the fertility, mortality and migration assumptions, other scenarios include "no change", which assumes that fertility and mortality rates will remain constant at current levels and "zero net migration", which allows the effects of the projected trends in fertility and mortality to be examined independently of the effects of migration.

List of available variants

The 2014-based variant population projections are based on the categories of assumptions shown in Table 1.2.

Table 1.2: Assumptions for the 3 components of demographic change

Fertility	Life expectancy	Net migration
Standard variants		
i High	High	High
ii Principal	Principal	Principal
iii Low	Low	Low
Special case scenarios		
iv Replacement 1	No improvement ¹	Zero
v Constant ¹		Long-term balanced (UK only) ¹

Source: Office for National Statistics

Notes:

1. Due to be published on 26th November 2015

From these categories of assumptions, the variant projections released on 29 October 2015 have been created as shown in Table 1.3.

Table 1.3: Variant projections

	Fertility	Life expectancy	Net migration
A Principal projection	Principal	Principal	Principal
Standard 'single component' variants			
B High fertility	High	Principal	Principal
C Low fertility	Low	Principal	Principal
D High life expectancy	Principal	High	Principal
E Low life expectancy	Principal	Low	Principal
F High migration	Principal	Principal	High
G Low migration	Principal	Principal	Low
Standard 'combination' variants			
H High population	High	High	High
I Low population	Low	Low	Low
K Young age structure ¹	High	Low	High
L Old age structure ¹	Low	High	Low
Special case scenarios			
O Replacement fertility ¹	Replacement	Principal	Principal
P Constant fertility ¹	Constant	Principal	Principal
Q No mortality improvement ¹	Principal	No improvement	Principal
J Zero net migration (natural change only)	Principal	Principal	Zero
R No change ¹	Constant	No improvement	Principal
U Long-term balanced net migration (UK only) ¹	Principal	Principal	Long-term balanced

Source: Office for National Statistics Notes: 1 Due to be released on 26th November 2015

The 2014-based projections for the UK projection have been calculated as the sum of the projections for the 4 individual countries (England, Wales, Scotland and Northern Ireland). Therefore, the projected population numbers, deaths at each age, and births at each age of mother for the UK are just the sum of those for the 4 individual countries. The "assumed" UK fertility and mortality rates are then "back-calculated" from these projected births, deaths and population numbers.

Previously some of the UK variant projections were "non-additive", that is, they were not calculated as the sum of those for the 4 individual countries. This change has been introduced partly as a result of the introduction of a new cross-border migration methodology and partly to meet a user requirement for variant projections for Great Britain.

6 . Summary of long-term assumptions

The new principal projections are based on the long-term assumptions of future fertility, mortality and net migration (that is, immigrants minus emigrants) and are summarised in Table 1.4. These have been agreed in consultation with NISRA, NRS and the Welsh Government. Comparisons are given with the assumptions made for the previous 2012-based projections.

Table 1.4: Long-term assumptions for the 2014-based national population projections compared with assumptions for the 2012-based projections

UK					
	United Kingdom	England	Wales	Scotland	Northern Ireland
Fertility – Long-term average number of children per woman					
2014-based	1.89	1.90	1.90	1.70	2.00
2012-based	1.89	1.90	1.90	1.75	2.00
Mortality - Expectation of life at birth in 2039 [*]					
Males 2014-based	84.1	84.3	83.4	82.3	83.3
Males 2012-based	84.3	84.5	83.8	82.2	83.5
Females 2014-based	86.9	87.1	86.4	85.0	86.5
Females 2012-based	87.5	87.8	87.1	85.7	87.0
Net international migration [†] – Annual long-term assumption					
2014-based	+185,000	+170,500	+4,000	+9,500	+1000
2012-based	+165,000	+150,000	+3,000	+12,000	0

Source: Office for National Statistics

Notes:

1. ^{*} Expectations of life for 25 years ahead given as specimen year. Note these are period expectations of life based on the mid-year mortality rates assumed for the year 2039 and do not take account of the continuing improvement in mortality projected beyond 2039.

2. [†] Net international migration does not include cross-border migration between the countries of the UK.

For the UK, the long-term assumption of average completed family size is 1.89 children per woman, the same as in the 2012-based projections. More information can be found in the [fertility assumptions](#) section of the release.

Assumptions on improvements in mortality are unchanged from the 2012-based projections. More information can be found in the [mortality assumptions](#) section of the release.

The new long-term assumption for net migration to the UK is +185,000 each year compared with +165,000 a year in the 2012-based projections. More information can be found in the [migration assumptions](#) section of the release.

7 . Changing state pension age

Pensionable ages for men and women

Full details about the current and planned changes to state pension ages under the Pensions Acts of 1995, 2007, 2011 and 2014 can be found in Appendix C.

Between 2010 and 2020, state pension age will change from 65 years for men and 60 years for women, to 66 years for both sexes:

- any woman born before 6 April 1950 will attain pensionable age when she reaches the age of 60
- for women born between 6 April 1950 and 5 December 1953, the date that pensionable age will be attained can be found in changing the pension age table 1.5
- for men and women born between 6 December 1953 and 5 October 1954, the date that pensionable age will be attained can be found in changing the pension age table 1.6

State Pension Age will then increase to 67 years for both men and women between 2026 and 2028:

- any person born after 5 October 1954 but before 6 April 1960 will attain pensionable age when he or she reaches the age of 66
- for persons born between 6 April 1960 and 5 March 1961 will reach their State Pension age at 66 years and the specified number of months that is shown in changing the pension age table 1.7
- any person born after 5 March 1961 but before 6 April 1977 will attain pension age when he or she reaches the age of 67
- for persons born between 6 April 1977 and 5 April 1978, the date that pensionable age will be attained can be found in changing the pension age table 1.8
- any person born after 5 April 1978 will attain pensionable age when he or she attains the age of 68

Sources: Pensions Act 1995 Chapter 26 Part II Section 126 and Schedule 4; Pensions Act 2007 Chapter 22 Part I Section 13 and Schedule 3; Pensions Act 2011 Part 1 Section 1 and Schedule 1; Pensions Act 2014 Part 3 Section 26 and Section 27.

The data presented in this bulletin do not reflect proposed further changes to the state pension age published by the government. They propose bringing forward the increase to state pension age to 68 by the mid-2030s and 69 by the late 2040s. These proposed changes are not yet law and still require the approval of Parliament. Further information relating to these proposals can be found on the [GOV.UK website](#).

Calculation of populations of working age and pensionable age for national population projections

Populations of working age and the pensionable age for national population projections are calculated in the following ways:

- from 2014 to 2020, the number of women aged 60 to 65 who are of pensionable age is calculated using changing the pension age table 1.9
- from 2014 to 2018, all men aged 60 to 64 are of working age and all men aged 65 to 70 are of pensionable age. From 2019 to 2020, the number of men aged 65 who are of pensionable age is calculated using changing the pension age table 1.10
- similarly, from 2021 to 2025, all persons aged 66 and over are of pensionable age. From 2028 to 2043, all persons aged 66 are of working age and all persons aged 67 and over are of pensionable age. From 2026 to 2027, the number of men and women aged 66 who are of pensionable age is calculated using changing the pension age table 1.11
- from 2046 onwards, all persons aged 68 and over are of pensionable age and all persons aged 67 are of working age. From 2044 to 2045, the number of men and women aged 67 who are of pensionable age is calculated using changing the pension age table 1.12

8 . National Population Projections expert advisory panel

An expert academic panel advises ONS early on in the assumptions-setting process on current and emerging demographic trends and their possible implications for the national population projections. This panel met in 2015 to advise on the assumptions for 2014-based population projections.

The membership of the panel for the 2014-based national population projections was as follows:

- Professor Ann Berrington, University of Southampton
- Ben Corr, Greater London Authority
- Professor Peter Goldblatt, University College, London
- Professor Carol Jagger, Newcastle University
- Doctor Nik Lomax, University of Leeds
- Professor Mike Murphy, London School of Economics
- Professor John Salt, University College London
- Professor Ludi Simpson, University of Manchester
- Doctor Chris Wilson, University of Oxford

Panel meeting

A note of the panel meeting held on 9 April 2015 is available in Appendix A.

Questionnaire

The panel completed a questionnaire where they were asked what they thought were the most likely future levels of fertility, life expectancy and migration. They were also asked for their views on the validity and importance of a wide range of arguments which might be thought likely to influence future trends. The questionnaire was originally devised by the International Institute for Applied Systems Analysis (IIASA) in Vienna and has been adapted by us for use in the UK. It is reviewed for each projection round to ensure that the experts' views on current and emerging trends are collected.

Details of the panel's views on the most likely levels of the total fertility rate, life expectancy at birth and total net migration to the UK (and associated 67% and 95% confidence intervals) in the years 2018 and 2038 can be found in Appendix B.

9. Background notes

1. Details of the policy governing the release of new data are available by visiting www.statisticsauthority.gov.uk/assessment/code-of-practice/index.html or from the Media Relations Office email: media.relations@ons.gsi.gov.uk

These National Statistics are produced to high professional standards and released according to the arrangements approved by the UK Statistics Authority.

2014-based National Population Projections (NPP)

Expert Advisory Panel Meeting

Room 060C, Skempton Building, Imperial College London, South Kensington Campus, London, SW7 2AZ

Thursday 9th April 2015, 10:30-15:00

Expert group

Prof. Ann Berrington, University of Southampton
Ben Corr, Greater London Authority
Prof. Peter Goldblatt, University College, London
Prof. Carol Jagger, Newcastle University
Dr Nik Lomax, University of Leeds
Prof. Mike Murphy, London School of Economics
Prof. John Salt, University College, London
Prof. Ludi Simpson, University of Manchester
Dr Chris Wilson, University of Oxford

ONS Population Statistics Division attendees

Oliver Dormon, Demographic Analysis Unit
Suzie Dunsmith, Population Projections Unit
Adrian Gallop, Demographic Analysis Unit and Government Actuary's Department
Paula Guy, Population Projections Unit (Secretary)
Jay Lindop, Deputy Director Population Statistics Division (Chair)
Julie Mills, Demographic Analysis Unit

Observers

Kirsty Maclachlan, National Records Scotland (audio link)
Luke Main, National Records Scotland (audio link)
Jos Ijpelaar, Northern Ireland Statistics and Research Agency (audio link)
Paul Vickers, ONS (audio link)

Apologies:

None

1. Introduction

1.1 Jay welcomed everyone to the meeting and thanked members for agreeing to be part of the 2014-based NPP expert advisory panel. The main aim of the meeting is to have an informed discussion about the long-term assumptions for the forthcoming UK-level population projections.

1.2 The role of the expert panel is strictly advisory. It was emphasised that ONS was not seeking a consensus where none exists and wanted to hear the full range of views on the key assumptions. Though all opinions would be considered, the final decision on the assumptions to be adopted for the next set of projections rests with the NPP committee which includes representatives from ONS and the devolved administrations.

1.3 The 2014-based population projections are scheduled for publication in October/November 2015.

1.4 Jay explained that ONS would give introductory presentations on each of the three sets of assumptions – fertility, mortality and migration, after which the floor would be open for general discussion.

2. Fertility

Introduction

2.1 Oliver Dormon's presentation began by reviewing the recent trends in period fertility including a comparison of the UK Total Fertility Rates (TFRs) with the TFRs for the 2010-based and 2012-based projections. Up to 2012 there had been a period of fairly stable TFRs so in the 2012-based projections this stability was assumed to continue into the future. However, there was an observed unexpected dip in the TFR in 2013 which was reflected in all 4 countries of the UK.

2.2 Oliver looked at the trends over time in the TFRs for the 4 constituent countries. The TFRs for England and Wales were very similar over this time period. Northern Ireland remained consistently higher than England and Wales, but has also been broadly stable since 2009. Scotland remained consistently below England and Wales, and has shown consistent decreases since the 2008 peak.

2.3 Trends in fertility rates for specific age groups were examined. It was noted that in 2013 there was a sharp decline in the age specific fertility rate (ASFR) for the 30-34 and younger age groups. The ASFR for those aged 35-39 was slightly lower in 2013 compared with 2012 but in the 40+ age group it was higher.

2.4 Oliver then presented the recent trends in cohort fertility. The completed family size (CFS) has declined gradually since the 1945 cohort. The most recent cohort to have completed fertility is the 1968 cohort who had 1.92 children on average, levels very similar to the 1965 cohort.

2.5 Looking at the fertility of the most recent cohorts relative to the 1968 cohort, Oliver explained that recent cohorts have experienced higher fertility in their teenage years but lower fertility in their early twenties than the 1968 cohort but they are partially catching up in their late twenties and thirties. The 1990 and 1995 cohorts have to date shown lower levels of fertility than the 1975-1985 cohorts but it remains to be seen whether this is due to postponement or if rates will remain at lower levels.

2.6 Oliver shared a graph focussing on the parity component of the TFR. This showed that there have been increases in births since 2001 of all orders. However first births have increased the most in terms of absolute contribution to the TFR. The graph also showed that the drop in the 2013 TFR was mainly due to a reduction in the number of first births.

2.7 Oliver summarised the key findings from the expert panel questionnaire responses. Experts' UK TFR estimates for 2038 ranged from 1.5 to 1.93, with an average of 1.82. This is broadly in line with the latest figure of 1.83. It was noted that at the expert panel meeting prior to the 2012-based projections the experts' average was 1.93. Based on the most recent data at that time, a TFR of 1.89 was adopted, an increase from the 1.85 TFR used in previous projections rounds. For 2018, there was a strong level of consensus with estimates ranging from 1.75 to 1.89, with an average of 1.83.

2.8 In terms of the experts' responses to questions regarding the forces and impacts of fertility, the majority of experts agreed that changes in population composition and differential trends in population subgroups and changing bio-medical conditions would result in a rise in fertility. There was some disagreement regarding the impact that the trend in ideal family size and (the strength of) individual desires for children would have. The

majority of experts agreed that changes in trends in patterns of education and work (including the proportion of time dedicated to the professional side of life) would result in a reduction in fertility. There was agreement that trends in income (including indirect income such as free childcare hours) and the changing nature and stability of partnerships, for example the rise of cohabiting parents, would have no overall impact.

Discussion

2.9 Panel members suggested that education enrolment or age at leaving education and whether this is set to continue might be a better predictor of future fertility.

2.10 In response to a question regarding to what extent the 2013 figure should be taken into account, there was general agreement that the data for one year cannot be considered a change in trend. Focus should be given to the longer term trend.

2.11 One member suggested that looking at trends since 1938 would be a better time frame as stability has been seen over that period. 30 years is a short time period. To consider variation a time period of relevance should be selected. Fertility was 1.8 in the 1930s and there has been below replacement fertility for 70 years.

2.12 Mention was made of the potential for anticipatory effects bringing forward births which is contrary to what is expected.

2.13 One member suggested that considering the UK as part of a suite of countries would result in more stable estimates, with different factors being taken into account for the 5 and 25 year estimates.

2.14 It was noted that the UN uses modelling for their projections, borrowing strength from neighbouring countries. Confidence intervals are produced automatically using this approach.

2.15 It was suggested that the focus should be on completed family size as these converge quite closely in comparison to the TFRs which are dependent on when people time their births. However, it was noted that the stability in completed family size hides a number of different trends such as childlessness for the higher educated being compensated by those of lower education. Comparability with other countries is not always possible. For instance, in Sweden those with higher education do catch up with their counterparts.

2.16 One member suggested there is benefit in choosing a figure for the future which is plausible rather than based on time series. Another expert would prefer an arithmetic calculation based on time series with expert input regarding what the relevant time series should be.

2.17 There was a discussion around whether the concept of cohorts is still relevant as mothers from overseas do not necessarily remain in the UK. Oliver confirmed that 26% of births are to non-UK born women and presented graphs showing a comparison of TFRs between UK and non-UK born women. It was noted that non-UK born women are not a heterogeneous group with some sub-groups having historically high fertility whilst others have low fertility rates. It was suggested that the year of entry to the UK should be taken into consideration.

2.18 There was a brief discussion around data quality. Oliver described the work undertaken by ONS regarding the misreporting of first births. Data from the Longitudinal Study was compared with registrations information. Analysis showed that 1 in 8 people were incorrectly reporting that this was not their first birth. There was also an implausible number of sixteen year olds reporting that they already have another child. Oliver has been working closely with the relevant registration organisations regarding how questions are asked and how answers are recorded. This will hopefully lead to an improvement in the quality of future years data.

2.19 There was a discussion regarding setting assumptions for the short and long term. It was noted that the two are separate with a different set of criteria to apply in the long term. There is an immediacy in the short term. Children born now will have an impact on future fertility rates. Environmental factors, immigration controls and the rates and characteristics of immigrants will all have an effect in the long term. Consideration needs to be given to what factors will change behaviours.

2.20 The regional variation in fertility rates was mentioned. It was noted that there was a drop in age specific fertility after the financial drop for Scotland, Spain, Italy and Greece. A similar trend was not observed in England. Scotland showed a distinct drop for those aged 20-34 but there was no explanation for this.

2.21 For the long term there was support for keeping the rates the same. The cohort of interest covers a stable period. If rates are changed there is a weight of responsibility which cannot hold. It was recognised that in the absence of a more sophisticated projections model, it is better to keep things simple and aim for plausibility.

2.22 Reference was made to a paper by David Coleman that notes there are various reasons as to why it is logical to have two children.

2.23 It was noted that there are aspects for which there is slightly more certainty. For instance, there is no reason to believe teenage pregnancies will increase. In the response to the questionnaire there was also consensus amongst the experts that births to women over 40 will continue to increase.

3. Mortality

Introduction

3.1 Julie Mills started the presentation by reviewing past trends in mortality. There was a slow increase in period life expectancy at birth for England and Wales at the end of the 19th century, followed by faster increases in the first half of the 20th century and a slow increase again from 1950 onwards.

3.2 The gap between male and female life expectancy at birth peaked at around 6 years in the late 1960s but figures have converged since then with life expectancy of birth in 2013 of 79.3 for males and 83.0 for females in England and Wales, a gap of 3.7 years.

3.3 Life expectancy at age 65 was relatively stable until the first half of the 20th century after which female life expectancy began to rise. Male life expectancy at age 65 is now increasing faster than for females, so the gender gap is closing. Julie explained that this is possibly due to differences in smoking patterns between males and females and the fact that men now undertake less physical work. In 2013 life expectancy at age 65 was 18.7 years for males and 21.1 years for females in England and Wales, a gap of 2.6 years. This compares with a gap of around 4 years in the 1970s and 80s.

3.4 Julie then compared life expectancy at birth internationally. Japan has the highest life expectancy at birth in the world at 86.6 years for females and amongst the highest for males at 80.2 years. This compares with figures for the UK of 78.9 years for males and 82.7 years for females. Four countries in total have exceeded 80 years for life expectancy at birth for males.

3.5 Moving onto looking at the major causes of mortality, Julie noted that the recent improvements have been driven by large falls in deaths from circulatory diseases since the early 1970s. Age standardised mortality rates for cancer are now higher than for circulatory diseases so will have a greater effect on future rates of mortality improvement.

3.6 Looking at the heat charts of mortality improvements, Julie highlighted the golden cohort. This cohort, born in the 1930s, has experienced higher improvement rates in every year than the surrounding cohorts for both males and females. However, Julie noted the emergence of potentially similar new cohorts with higher improvements born around the 1990s.

3.7 Adrian Gallop briefly described the methodology for the 2012-based assumptions as a four step process:

- estimate current rates of mortality improvement by age and gender
- set target rates of mortality improvement for the target year
- make assumptions on method and speed of convergence of current improvement rates to target rates and how improvement rates change after the target year
- apply successively to assumed base mortality rates

3.8 He then compared the assumed percentage changes in smoothed death rates between 2011 and 2012. Scotland (shown separately to the rest of the UK) was assumed to have lower levels of improvement at some ages.

3.9 Some potential drivers for future mortality change were described. These were:

- changes in bio-medical technology
- effectiveness of health care systems
- behavioural changes related to health:
 - decline in smoking prevalence
 - lifestyles
 - obesity
- emergence of new diseases (e.g. HIV, SARS)

- re-emergence of old diseases (e.g. TB)
- environmental change, disasters, wars
- change in population composition; cohort effects, migrants
- increasing resistance to antibiotics

3.10 The choice of the target rate of improvement was then addressed. Adrian noted that rates of improvement for the older ages are of most importance as these ages are where most deaths occur. Another factor to consider is that the standardised average rate of improvement for the age group 0 to 99 over the last 100 years was approximately 1.2% per annum and cohorts exhibiting the greatest improvement will be aged 100-110 in 25 years so would not contribute much to the overall rate of improvement in the target year. It was noted that there is continued debate as to whether future technical, medical and environmental changes will have greater or lesser impact than the past.

3.11 Adrian presented the UK percentage change in death rates between 2011 and 2012 by age attained in 2012 which clearly illustrated the higher improvement rates for the golden cohort. It was assumed that the 1930s cohort would continue to have higher improvement in the future.

3.12 Comparing actual and projected overall annual rates of mortality improvement for the UK over the same number of years, future rates over the next 49 and 79 years were broadly similar to those experienced over the past 49 and 79 years respectively. However, in the shorter term, there are some differences with an annual standardised rate of mortality improvement of 2.2% in the past compared to 1.8% projected for the future for males and 1.6% in the past compared to 1.9% in the future for females over the last/next 29 years.

3.13 Adrian then compared the ONS life expectancy projections with international comparators. ONS' life expectancy projections have historically been more optimistic than figures produced by Eurostat and the UN. The UK generally projected higher improvements than those by comparator countries. Looking at the projected period expectations of life at birth for 2060 for a selection of developed countries, those for Canada, the Netherlands, Austria and New Zealand are higher expectation than that for the UK for males. For females, France, Japan, Austria and New Zealand have a higher expectation of life than the UK.

3.14 Julie summarised the questionnaire results. In terms of the six forces, the majority of responses were either small changes, up or down, or little or no change. Experts felt obesity levels are likely to remain at similar levels and will have little effect on mortality. The only large upwards changes anticipated are as a result of changes in medical technology.

3.15 In terms of the target rate of improvement, the general opinion was that this should vary by age and be the same for males and females. There was some agreement for a rate of 1.2%, but suggestions varied between 0.9% and 1.7%. Julie noted that if we had a 1.7% target rate for males and 1.5% for females in the 2012-based projections (and higher rates for the golden cohort) this would result in period life expectancy at birth in 2060 of 89.0 for men and 91.1 years for women, compared to 87.0 and 90.1 respectively with an improvement rate of 1.2%. Most felt that the golden cohort improvement will reduce in the next 5-25 years.

3.16 In terms of period life expectancy, the average of the experts' opinions for the central estimate was 80.3 for males and 83.9 for females in 2018 and 84.9 for males and 88.2 for females in 2038 compared to 80.7 for males and 84.3 for females in 2018 and 84.2 and 87.5 in 2038 in the 2012-based projections.

Discussion

3.17 It was noted that users of projections are interested in the total number of births and deaths. The experts were keen to understand how sensitive the results are to cohort differences and changes in the assumptions. It was recognised that the numbers surviving into old age are key planning factors. Higher assumptions for death rates of those aged 85+ and 95+ would have a significant impact. Julie confirmed that a higher target rate for the golden cohort doesn't have a large impact. Differences in period life expectancy at age 65 with or without the higher target rates of improvement are less than 0.2 years. Adrian confirmed that a change in the improvement rate from 1.2% to 1.0% results in a reduction in life expectancy at birth in 2038 of 0.3 years for males and 0.2 years for females, which is also a small effect.

3.18 It was noted that the retirement age might have an impact on mortality and life expectancy. There will be fewer people suffering debilitating injuries. It was also noted that rates differ geographically. For instance, former mining areas tend to experience more disadvantage in terms of mortality. A similar parallel was drawn with the rapid deindustrialisation of Glasgow.

3.19 One member noted that internationally assumptions are diverse and suggested there is value in understanding life expectancy and mortality change within a suite of other countries for the long term. This system might be a more stable basis for projecting. Changes such as surgical procedures are common across countries. Adrian confirmed that a lot of countries use an extrapolation method. Last time the range of countries projections for life expectancy at birth were lower than the UK whilst later projections are more in line with those in the UK 2012-based projections.

3.20 It was suggested it would be useful to know early age morbidity. Any life effects of illness might be important. Life expectancy at age 65 will depend on the health of a person in their earlier life. Even small effects at young ages might have leverage. It was noted that in part this would be counterbalanced by improvements in medical technologies e.g. statins. This will depend on the type of illness. Those with some illnesses might be more likely to develop other health problems. An illness such as diabetes is monitored which might result in other issues being identified early.

3.21 There was a discussion regarding life expectancy at different ages. It was noted that looking at the lexis diagrams, different conclusions can be drawn. Most ages are improving. Few ages are as low as 1.2%. One member queried what the impact would be of continuing with the current values of improvement. Adrian advised that ONS used to produce a projection using a constant mortality improvement assumption but this resulted in an unusual pattern of mortality rates by age.

3.22 ONS looks at the mortality and life expectancy figures and makes some further adjustments. The projections were extended to age 125 to reflect the projected increase of those at very high ages. It was noted that the probability of those surviving at age 115 will increase as there is a body of people moving up from a range of ages. Adrian made reference to a recent Public Health England report which looked into the levelling off of mortality improvement at older ages and considered whether this was a blip or long term trend.

3.23 There followed some discussion regarding the life expectancy of the very old. This included the potential for there to be a change in the medical decision to keep a person alive, a change in social attitudes towards this issue or the wishes of patients being taken into account. One member noted that an assisted dying law might have a significant effect, although another noted that in the Netherlands the impact has been small as any extension of life tends to be for a short timeframe.

3.24 The impact of antibiotic resistance was discussed. It was suggested that this would make a small difference to the very old. It could occur as an epidemic but in these instances the remaining population tends to be less vulnerable.

3.25 Adrian asked members if they felt that an improvement rate of 1.2% was too optimistic. It was acknowledged that there are many factors which might impact on improvement rates and we can't hope to take these all on board. It was noted that the overall average has been constant for a long time and there needs to be good reason to deviate from this.

3.26 The continued ability of the NHS to treat patients was discussed. As an example one member noted that the life expectancy of those with diabetes has doubled but expressed doubt that this trend would continue due to the rise in the number of cases and the cost implications. Another member noted that affordability is counterbalanced. If the health of the elderly is not treated, social care services will need to be provided. Members suggested that improvements in life expectancy might be driven at age 60 and 70 or that more weight should be given to the early retirement years. Again it was noted that a rise in the statutory retirement age will have some effect.

3.27 In their response to the questionnaire, members responded that levels of obesity would stay the same and have no impact on life expectancy. It was noted that recent surveys have shown that more than 60% of the

population are classified as overweight or obese. Life expectancy for those with diabetes is on the increase. One member mentioned that there are models to project obesity; Public Health England has done some work in this area. In the long term, obesity amongst children has been shown to level off.

3.28 Adrian noted that the mortality rates for the old ages are not really impacted by migration and are not tied to the migration assumptions. Factors impacting the life expectancy of the population are likely to be the same for migrants as those born here. It was also suggested that those who migrate are often the healthiest of their country.

3.29 Adrian said that the variant mortality projections assume target rates of 2.4% and 0% per annum in 2038 with higher rates for those born in the 1930s as for the principal projection. Adrian explained that users are encouraged to look at the high and low life expectancy variants to see how sensitive the projections are. These variants are not bounds. One member noted that for the principal figures, factors counterbalance. ONS might need to be more explicit as to the reasons behind the high and low values to justify these assumptions. There is nothing to suggest that the trajectory should be changed but more context should be added. It was noted that quantifying differences is harder than producing qualitative arguments in support of the variants.

3.30 One member noted that the UN probabilistic model might be easier to justify to the panel but not to users.

3.31 One member noted that deaths and population numbers matter more to users. Linking state pension age to life expectancy would provide interesting information about social class differentials. This will mean that future mortality projections would come under greater scrutiny.

4. Migration

Introduction

4.1 Suzie Dunsmith started her presentation by looking at the UK migration assumptions for the 2012-based National Population Projections and how this compared to historic trends and migration estimates. The long term UK principal migration assumption was set at 165,000 per annum, with high migration and low migration of +/- 60,000. In the first year of the principal projection, the figures were 17,500 below and in the second year 94,500 below the migration estimates subsequently published. The latest migration figure is for the year ending September 2014 which estimated a 298,000 net inflow to the UK.

4.2 UK net migration followed an upward trend from 1997, to a peak of 273,000 in 2007. It dropped from 2010 to 2011 and 2012 but rose again in 2013. Suzie noted that the net international migration figures were revised after the 2011 Census, but the corresponding in and outflows were not amended.

4.3 Approximately half of all immigration to the UK is from non-EU citizens, about two fifths is from EU citizens and the remaining immigration is made up of British citizens. The top five countries of previous residence are China, Spain, India, Australia and Poland. Work and study have been the main reasons for immigration in the recent past with work becoming a more popular reason to migrate than study.

4.4 In terms of UK emigration, about 40% is by British citizens, a third is from non-EU citizens and the remaining emigration is by EU citizens. The top five countries of next residence are Australia, USA, Spain, China and France, with the main reason for emigration being work-related.

4.5 Suzie summarised the main findings of the questionnaire in terms of the main drivers for migration.

4.6 Experts felt that political instability around the world would not have a big impact.

4.7 For environmental change, members anticipated little or no effect in the short term and no effect or a small /large upwards movement in the long term. It was felt that economic factors would impact more and inflows would be dependent on government policies. One member felt that the UK is more likely to be affected by growing aridity and associated effects in southern Europe. This would result in fewer British people wishing to emigrate there whilst there would be more people from southern Europe preferring to move north.

4.8 The responses to the impact of the changing global economy were more mixed with the majority of experts expecting a small upwards movement in migration over the next 5 years. In the long term, there was a spread of responses between a small downwards and large upwards movement. In the long term the relative attractiveness of the UK was questioned. It was felt that European economies might not be stronger than China, India, some African states and Brazil and the recovery in other European countries might reduce the pressure of migration to the UK. Over 25 years, it was felt that the use of advanced communication and other technologies will reduce the necessity for much of the project-based movement that currently takes place.

4.9 Other factors suggested by experts that might impact on migration included government policy, EU membership, the need for labour to support the elderly population, an increase in alternatives to a UK higher education and a reduction in the demand from other countries for UK emigrants.

4.10 Suzie reported on the analysis of the questionnaire responses. For the long term, the experts' average central estimate for UK immigration was 530,000 with an average 95% confidence level of 309,000 to 750,000. This compares with the latest estimate of 526,000. For international emigration, the average central estimate was 383,000 with an average 95% confidence level of 256,000 to 531,000, compared to the latest estimate of 317,000. For net international migration the average central estimate was 153,000 with an average 95% confidence level of 0 to 377,000. Suzie noted that this was a lower figure than the last two expert panel meetings had suggested and compares with the latest estimate of 209,000 (year ending December 2013). Three experts thought it possible there could be negative UK net migration in the long term.

4.11 The central estimates for short term in, out and net migration were 535,000, 355,000 and 188,000 respectively. It was noted that the 95% confidence interval for one expert includes the potential for negative net migration in the short term.

Discussion

4.12 Members of the panel were invited to discuss the factors impacting on future migration.

4.13 One member felt the factors influencing migration are students, internationalisation and the economy of other countries e.g. the Eastern European economy improving. The politics of migration also have an impact. The

government can control levels of migration and there is a likelihood that migration will reduce in the long term as services are not sustainable. The expert felt that although free movement will not stop, the drivers will diminish and in the long term forces will not continue at the same level.

4.14 It was suggested that social networks attract large numbers of migrants e.g. Indians. Polish migrants come to the UK for different reasons. Reference was made to Tony Champion's work on onward migration which identified that some migrants go to Bristol for the good job prospects whereas Indians go to areas such as Birmingham to be with family.

4.15 Another expert noted that there are pull factors leading to circulatory migration. In future there will be a larger population requiring care services and consideration needs to be given to whether there are enough people to do these jobs. Short term employment contracts might be issued resulting in people from outside the UK coming for a short period of time. Consideration needs to be given to how public services might change, the skill levels of the UK-born population for high skilled roles and how difficult it might be to fill low skilled jobs.

4.16 It was noted that in the past there were low levels of productivity in the UK economy. For certain sectors, cheap labour came into the country and capital investment stopped. There is scope for some low level jobs to be filled by increased productivity and capital investment.

4.17 One expert highlighted the fact that the development of new IT methods that allow remote access will impact on migration. There is likely to be an increase in virtual, rather than physical, movement.

4.18 Environmental changes worldwide will have an impact on migration. There might be movements of populations e.g. in Africa.

4.19 One expert anticipated that in and out migration will remain high but that net migration will fluctuate over time with the economic cycle and that fluctuations will determine the long term trend. Economic factors are key in the short term and this expert does not believe that migration will drop drastically from now.

4.20 Another believes that in the long term there will be more movement for economic purposes but the UK will receive a smaller share of migrants as it will be competing against other countries. In the short term, the UK will keep outgrowing the EU with no expectation that will stop as long as the UK remains part of the EU.

4.21 It was noted that there is a global spread in the use of the English language e.g. Spain. There is a pool of people who want to go to English speaking countries. The whole world opens up to a common language.

4.22 One member suggested that a combination of economic self interest, social networks and existing flows explains variation globally. A proportion of migrants are accompanying dependants and this is a self sustaining process that will be secular. It was recognised that the larger the stock of migrants, the more attractive the location. It was noted that with the sponsorship system there was a cap on Tier 2 visas but the number of Tier 2 visas being extended has increased considerably. In the points based system people could previously come for 3 years, now it is 5 years. There have been many extensions, more being for dependants than principal applicants.

4.23 It was noted that the UN figures for the past 40-50 years show Europe and North America with growing net in migration. Africa, Asia and Latin America have increasing net out-migration. There is inequality economically in the world so the levels of net immigration will continue to diverge. The trends seem to suggest a growing gain to Europe including the UK.

4.24 There was acknowledgement that it is difficult to predict what will happen. Views are polarised and there is no consensus.

4.25 A point was made regarding the impact on aid structures. The minority of migrants will stay a long time. A bigger minority staying on impacts on the older population, with the proportion staying having a cumulative effect.

4.26 It was noted that for London and the South East, 40% of the rise in population of the 18-35 cohort is due to migration. A third of the population of England lives in London and the South East. As social and economic factors differ by region, it was suggested that migration assumption setting should be undertaken at a regional level. Suzie described modelling work undertaken by ONS to trial setting migration assumptions for London and the South East, separate to the rest of the UK. This work concluded that the migration assumptions were no different than if they had been set nationally.

4.27 It was noted that looking at recent trends by origin, there are pressures from Spain, Greece and Italy. The focus has tended to be on Eastern Europe. In the short term, the push from the rest of Europe is important. In terms of migration from China, the regulations regarding students are important.

4.28 Suzie described the changes that will be implemented in the 2014-based projections from using cross border migration rates, instead of flows, between countries of the UK. She also sought experts' views on the

option to apply an adjustment to the rates, similar to the method recently adopted by Statistics Canada, to ensure migration figures are responsive to the projected size of each of the UK countries.

4.29 Experts agreed that a migration adjustment should be applied. The cross border migration numbers are fairly stable. Applying the adjustment maintains this stability. It was also noted that an adjustment makes sense logically as growing areas become more attractive to migrants.

4.30 Suzie invited the views of members to setting the UK migration high and low variants additively rather than non-additively in the 2014-based projections. One expert agreed that it is mathematically necessary for this to happen so the overall error is the sum of the constituent countries. However, another member noted that by doing this the assumption is that migration is at its highest/lowest in all four countries simultaneously which is unlikely and would result in variants wider than expected.

4.31 There was some discussion regarding the number of immigrants that report their residence as being London on the IPS, but who subsequently move out of the capital. One member felt that in the projections methodology there is nothing that relates international migration with cross border moves and historic cross border rates would not fully capture these patterns. It was noted that these movements should be picked up through GP registrations, although that is dependent on individuals actively registering with a doctor. One member confirmed that there are new migrant ciphers on the NHSCR. Although it is not possible to determine when a migrant arrived, it can be used to identify the number from abroad who moved out of London.

4.32 Suzie asked the experts to consider whether the opposing forces would result in an increase or decrease to future international migration levels. One member suggested fitting a regression line to the upwards trend. Others believed that the high net figure has been observed for a relatively short timeframe and that a linear trend could not continue. Another noted that net migration is cyclical due to returning migrants.

4.33 It was suggested that the individual routes of entry (student, labour, asylum or family) could be considered. People move for different durations of time. Consideration also needs to be given to what is likely to happen in terms of family migration such as the need to speak English and the dependants of migrants. The political agenda places restrictions on family, working and student migrants.

4.34 Experts generally felt that levels of emigration will increase. The graph presented by Suzie showed that 40% of emigration from the UK is by British citizens and 60% is by those born overseas. It was noted that as the numbers born overseas increase, there will be a larger number of people to emigrate.

4.35 It was noted that the UK education system is becoming increasingly dependent on international students. Other countries are now seeking to attract students from overseas. For example, Kazakhstan is now offering courses in English and students from China are seeking lower fees.

5. AOB

5.1 Suzie outlined the next steps in the process:

- minutes to be sent to the panel for checking and an anonymised version to be published with the release
- teams to set assumptions
- consultation with users
- NPP Committee to agree long term and set short term assumptions
- projections run
- publication in October/November 2015

5.2 Jay thanked members for attending the meeting and for their valuable input and informative discussion.

11. Appendix B: Analysis of the results of the NPP expert advisory group questionnaire

The National Population Projections (NPP) Expert Advisory Panel of 9 academic demographic experts met in April 2015. In an accompanying questionnaire, they were asked for their opinions on the likely future levels and trends in fertility, mortality and migration. This report summarises the main findings.

Fertility

The experts were asked for their views on UK fertility trends over the next 25 years.

Expert assessment of long-term UK fertility level

The experts were asked for their views on the most likely level of the total fertility rate (TFR) in 2038. Eight out of nine experts thought that the TFR would be between 1.80 and 1.93 in 2038, with one expert estimating a lower TFR of 1.50.

There was no consensus among the experts around exactly what the TFR would be in 2038, and all commented on the difficulty of predicting TFR into the future, given the range of conflicting forces.

The average TFR predicted for 2038 was 1.82, a similar level to the 2013 estimate, but substantially lower than the average experts' predictions from previous projection rounds. This is also lower than the 2012-based projection of a TFR of 1.89 in 2038, which may imply that there is evidence for decreasing the long-term assumption. However it is worth noting that the membership of the panel changed between projection rounds, so it is unclear whether this increase is due to different experts making up the panel, or a change in the experts' views.

On average, experts believed that there was a 67% chance of the TFR in 2038 lying between 1.60 and 2.09 and a 95% chance of it lying between 1.39 and 2.32, though these figures for the 95% confidence interval were affected by one expert's very large confidence interval estimate. (Figures 1.1 and 1.2).

Figure 1.1: Respondents' estimates of the TFR in 2038 (and associated 67% confidence intervals)

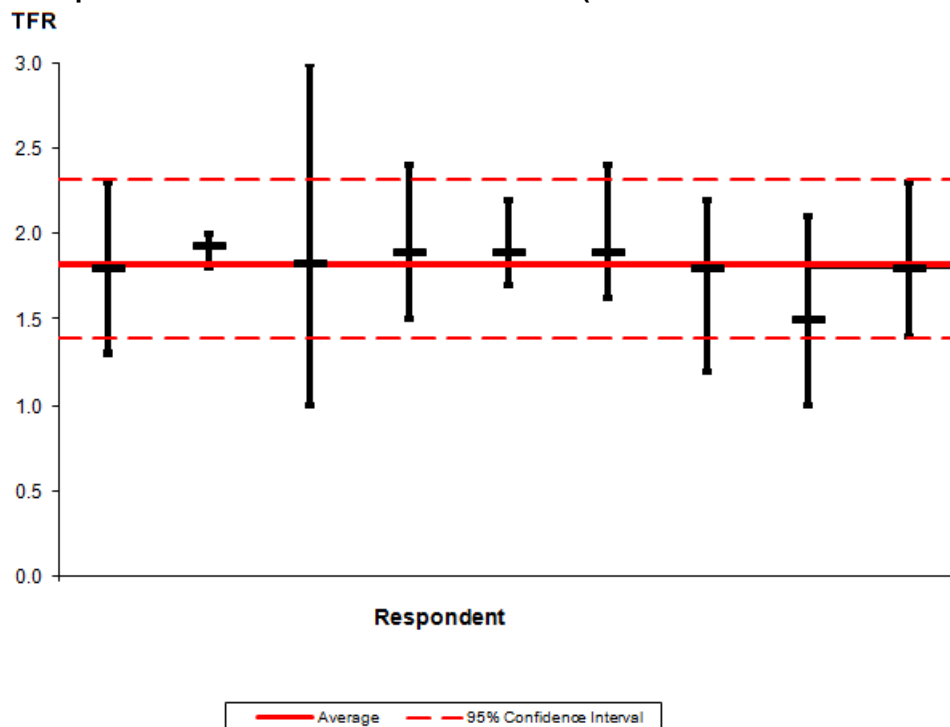

Figure 1.2: Respondents' estimates of the TFR in 2038 (and associated 95% confidence intervals)

Expert assessment of UK fertility trends in the short-term

The advisory panel was asked to assess the likely trend in fertility up to 2018 with reasons and to estimate the likely TFR in 2018.

Likely short-term trends in fertility

In terms of likely trends in age-specific fertility rates up to 2018, all experts believed that age specific fertility rates (ASFRs) for women under 20 would stabilise or decrease further. There was no consensus on the likely short-term ASFR trend for women in their 20s but no expert felt it would change substantially. Experts believed that fertility would continue to increase, or stabilise, for women in their 30s. All experts agreed that there would be an increase in ASFR for women aged over 40.

Quantitative estimates for 2018

The 9 experts were asked to quantify the most likely level of the TFR in 2018, together with plausible ranges which would cover roughly 67 and 95% of possible values. Figures 1.3 and 1.4 show the predictions for 2018.

Estimated TFRs for 2018 ranged from 1.75 to 1.89. Four were between 1.85 and 1.90, and 3 experts predicted 1.80. Other experts' estimates were 1.75 and 1.83. The mean was 1.83, a slightly lower prediction to the experts' 2012 projection round average of 1.89 in the short term.

Figure 1.3: Respondents' estimates of the TFR in 2018 (and associated 67% confidence intervals)

Figure 1.4: Respondents' estimates of the TFR in 2018 (and associated 95% confidence intervals)

On average, experts believed that there was a 67% chance of the TFR lying between 1.75 and 1.93 in 2018 and a 95% chance of it lying between 1.68 and 2.00. This underlines the uncertainty inherent in estimating future fertility, even within a short timescale.

Underlying forces that may influence future fertility

The advisory panel was asked to consider 6 forces with the potential to affect fertility levels in the long-term (to 2038). By considering a range of arguments within each force they were asked to assess the overall likely impact on future family size. The experts emphasised that the effect of some forces were complex and sometimes conflicting.

“Changing bio-medical conditions, such as new or greater use of assisted reproductive technologies” was the force that had the greatest consensus amongst experts. The majority felt that this would have an increased impact on fertility, with others having the opinion that this would have little or no effect. One expert believed that the increase in fertility would be due to the increase in success in medical breakthroughs such as freezing eggs.

“Changes in population composition and differential trends in population subgroups, for example the fertility of non-UK born groups” was the force that experts felt would have the greatest impact on fertility, with all but one expressing a direction of impact. However, the effect of this was slightly conflicting with 6 experts of the opinion that this would have a small upwards effect, one a large upwards effect, one small downwards, and one with little or no impact. One expert commented that the driver of environmental change may result in more immigrants from poorer regions who have high fertility.

The force “Trends in patterns of education and work (including the proportion of time dedicated to the professional side of life)” also had a divided opinion with 5 experts believing that this would have a small downwards impact, 3 felt it would have little or no impact, and one a small upwards impact on fertility. One expert believed that the strongest driver on future fertility trends would be the relationship between women and work, and that the downward impact on fertility would be due to the desire for paid labour in order to avoid unpaid reproductive labour.

The 2 forces “Trend in ideal family size and (the strength of) individual desires for children” and “Trends in income (including indirect income such as free childcare hours)” had a divided opinion across the panel on the impact on fertility. Approximately half of the experts agreed that either force would have little or no effect. The remainder were divided between small upwards and downwards impacts. It was discussed that Government policies on family allowances and benefits levels would have an effect on fertility.

The final force, “Changing nature and stability of partnerships, for example the rise of cohabiting parents” were felt by the majority of experts to have little or no net impact on fertility rates. This does not mean that the forces would not have some effect, but that the effects they have will be minor, or will be conflicting.

In addition to the forces ONS asked the experts about, they were invited to supply any other forces they felt would be important in shaping future fertility. Government policies such as provision of paid paternity leave and increased subsidisation of childcare were believed to impact on fertility. In addition, policies regarding teenage sexual health, for example, abortion, provision of free contraception and wide availability of contraception (including emergency contraception) were further government-related forces. Housing shortages and rent prices, and environmental impacts (of climate change worldwide, connected to migration) were also felt to be factors that could affect UK fertility in the long-term, as well as the impact of same sex marriages and surrogacy.

Mortality

The experts were asked for their views on expectations of life at birth in the UK, and on a series of arguments that might be thought likely to influence mortality, either upwards or downwards.

The average response by the experts for period expectation of life at birth in 2038 was 84.9 years for males and 88.2 years for females. One expert did not respond to the question. These compare with the 2012-based projection for 2038 of 84.2 years for males and 87.4 years for females. There was some divergence of views with regard to life expectancy for both male and females between the experts, with 2 of the 5 estimates being outside the 67% confidence interval for the group average for males, and one estimate outside the confidence interval for females (Figure 1.5 and 1.6).

Figure 1.5: Respondents' estimates of period life expectancy for males in 2038 (and associated 67% confidence intervals)

Figure 1.6: Respondents' estimates of period life expectancy for females in 2038 (and associated 67% confidence intervals)

The majority of the panel was optimistic about future mortality improvements although they had differing views about period expectation of life at birth continuing to rise at the same rate as that seen over the last decade or so. Most were of the opinion that the rates of improvement in male mortality should be higher or maintained at 1.2% per year. One of the experts thought that the rates of improvement for males should be lower than 1.2%. The opinions were the same with regard to rates of improvement in female mortality.

The main force thought most likely to affect future mortality levels was changes in bio-medical technology. The majority opinion of the expert panel was that this force should have a small upwards influence on life expectancy, with 3 experts reporting a large upward influence for this force.

The experts generally felt that environmental change, disasters and war would have little or no influence on life expectancy. They were also of the opinion that changes in population composition and differential trends in population sub-groups would have little impact. The majority of the panel thought that the level of obesity in the UK will remain at a similar level over the next 25 years.

Migration

The experts were asked about their views on the levels of international migration to and from the UK in 2018 and 2038 (that is, 5 years and 25 years into the future from the 2013 estimates, which were the latest available at the time).

Experts' views on migration in the long-term

With respect to immigration to the UK, 4 experts thought that the level in 2038 would be lower than the average of 2009 to 2013 estimates (that is, between 350,000 and 500,000 per year), 3 experts thought that the level would be higher (between 590,000 and 600,000 per year), and one thought it would be significantly higher (700,000 per year). One expert did not respond to the question. The average response for the expected level of annual immigration to the UK in 2038 was 530,000, with an average 67% confidence interval of 369,000 to 643,000.

With respect to emigration from the UK, 6 experts thought that the level in 2038 would be roughly similar to the average of 2009 to 2013 estimates (that is, between 300,000 and 400,000 per year), whilst 2 thought it would be higher (between 450,000 and 500,000 per year). One expert did not respond to the question. The average response for the expected level of annual emigration in 2038 was 383,000, with an average 67% confidence interval of 293,000 to 471,000.

The average annual net migration derived from the experts' responses for 2038 was a net inflow of +153,000 per year (with an average 67% confidence interval of 69,000 to 315,000). This is a smaller figure than the 2012-

based long-term assumption for net migration to the UK of +165,000 per year. Net international migration to the UK derived from the experts' assessment of likely levels of immigration and emigration in 2038 are shown in Figure 1.7, together with associated 67% confidence intervals.

Figure 1.7: Respondents' estimates of total net migration in 2038 (and associated 67% confidence intervals)

The experts were also asked to consider 3 overall forces with the potential to affect levels of net migration to the UK in the long-term and assess the importance and likely impact of each force upon future migration:

- the continuing instability of Syria, Ukraine, and other regions
- environmental change
- the relative attractiveness of the UK in a changing global economy

The majority of experts considered the first force to have an upwards impact on total net migration, with 4 experts stating this would have a small upwards effect, 2 a large upwards effect, and 3 little or no effect on total net migration. Forces 2 and 3 were perceived to have less of a large influence. Five experts considered the environmental change force to have little or no effect, 3 a small upwards effect, and one a large upwards impact on total net migration. There was most disagreement with the third force, where 3 experts felt this would result in a small upwards impact, one a large upwards, 2 a small downwards impact, and the remainder little or no impact on total net migration. Other forces identified by the experts were UK government policies (including employment and border controls), EU regulations and membership and education trends.

Experts' views on migration in the short-term

With respect to immigration to the UK, 8 experts thought that the level in 2018 would be roughly similar to that estimated for 2013 (that is, between 500,000 and 600,000 per year). One expert did not respond to the question. The average response for the expected level of annual immigration to the UK in 2018 was 535,000, with an average 67% confidence interval of 437,000 to 609,000.

With respect to emigration from the UK, 8 experts thought that the level in 2018 would be roughly similar to that estimated for 2013 (that is, between 300,000 and 400,000 per year). One expert did not respond to the question. The average response for the expected level of annual emigration from the UK in 2018 was 355,000, with an average 67% confidence interval of 303,000 to 393,000.

The average annual net migration derived from the experts' responses for 2018 was a net inflow of +188,000 per year (with an average 67% confidence interval of 129,000 to 274,000). This is somewhat higher than the

corresponding experts' average for 2038 (+153,000 per year). Net international migration to the UK derived from the experts' assessment of likely levels of immigration and emigration in 2018 are shown in Figure 1.8, together with associated 67% confidence intervals.

Figure 1.8: Respondents' estimates of total net migration in 2018 (and associated 67% confidence intervals)

1 . Introduction

This report provides a brief summary of the results of the 2014-based national population projections for the UK and provides additional charts and summary tables illustrating the results of the projections. For discussion of the results see the [statistical bulletin](#).

Included are sections on:

- results, which can also be examined using the [interactive population pyramids](#), which allow comparisons of the projected age structure up to mid-2039
- the role of migration in population growth
- comparison with the results of the 2012-based national population projections
- charts for the UK and constituent countries, which are available in the appendices, showing:
 - estimated and projected total population, year ending mid-1971 to year ending mid-2089
 - estimated and projected births and deaths, year ending mid-1971 to year ending mid-2089
 - percentage age distribution for the period, year ending mid-1971 to year ending mid-2089
 - estimated and projected total population for the principal and key variant projections, year ending mid-1981 to year ending mid-2039
 - change in the projected population at 2039 by age and sex compared with the 2012-based projections

2 . Summary of results

Results

The UK population is projected to increase gradually from an estimated 64.6 million in mid-2014 to reach 74.3 million by mid-2039. Of the projected 9.7 million increase between mid-2014 and mid-2039, approximately 4.7 million (49%) is due to projected natural increase (more births than deaths) while the remaining 5 million (51%) is the assumed total number of net migrants.

Summary results tables

Table 2.1 presents a summary of the projection results by components of change from mid-2014 to mid-2039, for the UK. The equivalent tables for the constituent countries of the UK, England and Wales, and Great Britain can be found in the data download of this table.

Table 2.1: Components of change: summary (annual average), UK, mid-2014 to mid-2039

	Thousands					
	2014-15	2015-20	2020-25	2025-30	2030-35	2035-39
Population at start	64,597	65,097	67,360	69,444	71,353	73,044
Births	776	796	810	803	801	815

Deaths	605	566	578	606	648	690

Charts of summary results

This section presents charts for the UK for the year ending mid-1971 to the year ending mid-2089. The equivalent charts for the constituent countries of the UK are available in the appendices A to D.

Figure 2.1 presents the estimated and projected total population in the UK between mid-1971 and mid-2089 and shows that the population is projected to continue to rise gradually over the period to mid-2089.

Figure 2.1: Estimated and projected total population, UK, year ending mid-1971 to year ending mid-2089

Source: Office for National Statistics

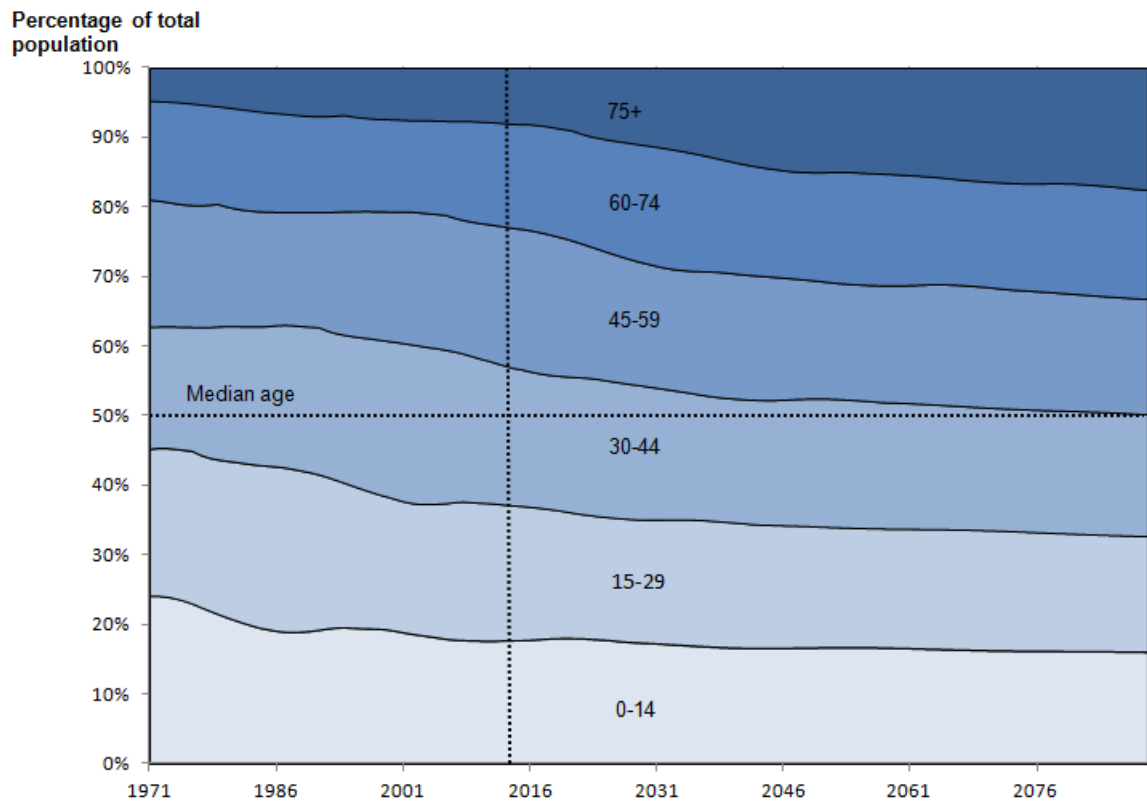

Figure 2.2: Estimated and projected births and deaths, UK, year ending mid-1971 to year ending mid-2089

Source: Office for National Statistics

Figure 2.3 shows how the age distribution of the UK is projected to change, illustrating how the median age of the population increases through the projection period.

Figure 2.3: Percentage age distribution, UK, year ending mid-1971 to year ending mid-2089

Variant projections

Table 2.2 presents projections of the total population under the principal projection, standard variant projections and special case scenarios for the UK and its constituent countries in mid-2039. Three additional measures are also included: the percentage of the population under 16, percentage of population 65 and over, and dependants per 1,000 persons of working age.

A further 7 variant projections (2 standard variants and 5 special case scenarios) are due to be released on 26 November 2015.

Table 2.2: Measures of population structure under the principal projection, standard variant projections and special case scenarios, UK, mid-2039

Projection	Total population (000s)	% of population aged under 16	% of population aged 65 & over	Dependants per 1,000 persons of working age*
Principal projection	74,284	17.8	24.3	666
SINGLE COMPONENT VARIANTS				
High fertility	75,765	19.0	23.8	689
Low fertility	72,504	16.4	24.9	642
High life expectancy	75,051	17.6	25.0	680
Low life expectancy	73,488	18.0	23.6	652
High migration	76,786	18.0	23.7	654
Low migration	71,783	17.6	25.0	679
COMBINATION VARIANTS				
Largest/smallest total population size				
High fertility, High life expectancy, High migration	79,090	19.0	23.8	691
Low fertility, Low life expectancy, Low migration	69,273	16.4	24.9	640
SPECIAL CASE SCENARIOS				
Zero migration (natural change only)	67,658	16.8	26.3	690

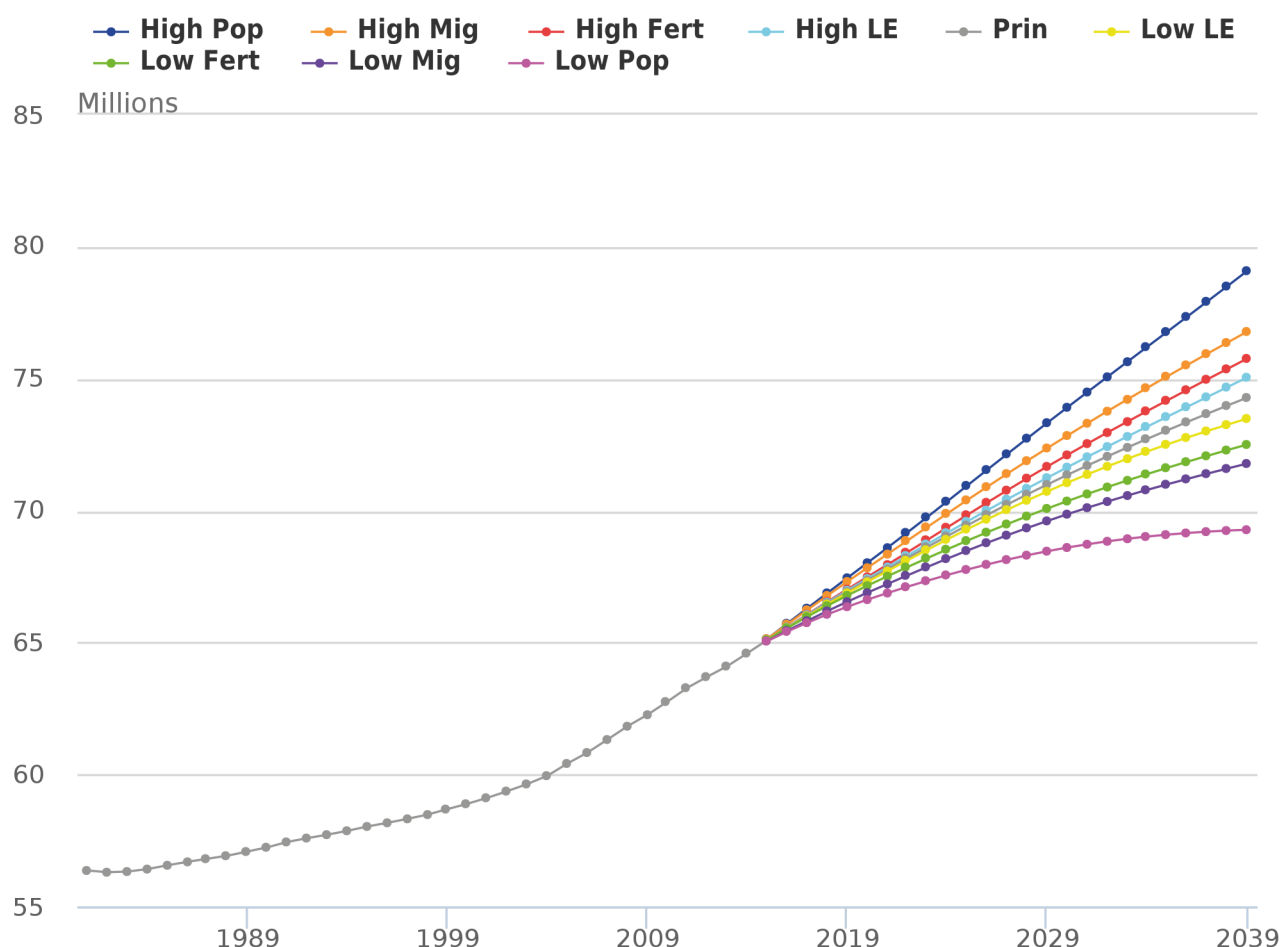

Source: Office for National Statistics

Notes:

* Dependants are children under 16 and people of state pensionable age and over. Working age and pensionable age populations are based on state pension age (SPA) for given year. Between 2012 and 2018, SPA will change from 65 years for men and 61 years for women, to 65 years for both sexes. Then between 2019 and 2020, SPA will change from 65 years to 66 years for both men and women. Between 2026 and 2027 SPA will increase to 67 years and between 2044 and 2046 to 68 years for both sexes. This is based on SPA under the 2014 Pensions Act.

Figure 2.4 shows the actual and projected population for the UK between mid-1981 and mid-2039, by principal projection and selected standard variants.

The equivalent charts for the constituent countries of the UK can be found in the relevant appendices.

3 . Migration and population growth

deaths and because of positive net migration. However, the components of population change are not independent of each other. In particular, the projected numbers of future births and deaths are themselves partly dependent on the assumed level of net migration.

An understanding of the overall effect of migration on population growth can be obtained by comparing the results of the principal and main variant projections with those of the zero net migration ("natural change only") variant projection. The zero net migration variant assumes that net migration will be zero at all ages in future, but makes the same assumptions about fertility and mortality as the principal projection. In this analysis, the effect of net migration on population growth in the period to mid-2039 is considered.

If annual net inward migration to the UK was to average 185,000 a year (the long-term assumption in the principal projection) this would lead to a total net inflow of 4.625 million migrants in the period between mid-2014 (the base year of the projections) and mid-2039. In fact, the projected total number of net migrants during this period in the principal projection is slightly higher (4.96 million) due to the higher migration assumptions for the first few years of the projection.

The assumed fertility and mortality rates are the same in the principal projection, the zero net migration variant projection and the high and low migration variants. However, because migration is concentrated at young adult ages, the different assumed numbers of migrants affect the number of women of childbearing age and hence the future number of births.

There is no comparable effect on deaths, at least in the period to mid-2039. At ages over 35, assumed net migration flows fall considerably in the principal projection and the high and low migration variants so the projected number of deaths over the period to mid-2039 is similar under all the migration variants.

Table 2.3 shows the projected components of population change in the period to mid-2039 in the principal projection, the high and low migration variants (which assume long-term annual net inward flows of 265,000 and 105,000 a year respectively), and the zero net migration variant projection.

Table 2.3: Projected population change, UK, mid-2014 to mid-2039

	Thousands			
	High migration variant	Principal projection	Low migration variant	Zero net migration variant
Population at mid-2014	64,597	64,597	64,597	64,597
Population change (2014-39)				
Births	20,677	20,087	19,498	18,304
Deaths	15,408	15,360	15,312	15,242
Natural change	5,269	4,727	4,186	3,061
Net migration	6,920	4,960	3,000	0
Total change	12,189	9,688	7,186	3,061
Population at mid-2039	76,786	74,284	71,783	67,658

Source: Office for National Statistics

Table 2.4 shows how the projected population growth is broken down between the assumed level of net migration and projected natural change.

Table 2.4: Projected population growth by component, UK, mid-2014 to mid-2039

	Thousands		
	High migration variant	Principal projection	Low migration variant
Total population increase between 2014 and 2039	12,189	9,688	7,186
Resulting from:			
Assumed net migration	6,920	4,960	3,000
Natural change assuming zero net migration	3,061	3,061	3,061
Additional natural change from assumed level of net migration	2,207	1,666	1,124

Source: Office for National Statistics

In the principal projection, the population of the UK is projected to grow by 9.7 million between mid-2014 and mid-2039. Some 5 million of this increase is directly due to the assumed number of net migrants. Natural change accounts for a further 4.7 million — the difference between 20.1 million births and 15.4 million deaths. Just over 3 million of this natural change (increase) would occur with zero net migration. The remaining 1.7 million is the net effect of the assumed annual level of net migration on natural change (almost entirely the effect on births).

Some 51% of population growth in the principal projection is therefore directly attributable to the assumed number of net migrants. The remaining 49% is attributable to projected natural change (of which 32 percentage points would occur with zero net migration and 17 percentage points arise from the effect of net migration on natural change). In total, therefore, some 68% of population growth in the period to mid-2039 in the principal projection is attributable, directly or indirectly, to future net migration.

It should be emphasised that these calculations are based on comparing alternative projections which make the same assumptions about future fertility and mortality rates irrespective of the assumed level of net migration. In practice, fertility and mortality rates for new migrants are likely to differ, to some extent, from those for the existing population.

Note that the principal projection and the zero net migration variant projection for the UK are calculated by aggregating equivalent projections for the 4 constituent countries of the UK. The resulting UK level fertility and mortality rates are therefore effectively weighted averages of those for the individual countries. This leads to some very small differences at UK level between the effective fertility and mortality rates used in the principal projection and the zero net migration variant. This has no significant effect on the analysis in this section.

4 . Comparisons with previous projections

Base population

Overall, the published mid-2014 population estimate for the UK is 86,000 (0.1%) higher than the 2012-based projection of the population at mid-2014.

Projected future population

The projected population of the UK at mid-2039 is about 419,000 (0.6%) higher than in the 2012-based projections. This is because the population of the UK is projected to grow at a faster rate in the 2014-based projections than the 2012-based projections. This is mainly due to the 2014-based projections assuming higher levels of international migration.

At mid-2039, populations are projected to be lower than in the 2012-based projections for Scotland and Wales but slightly higher for England and Northern Ireland. The percentage difference by mid-2039 is greatest for Scotland (1.8% lower) where the projected levels of births and net migration have fallen. The projected population of Wales is 1.5% lower than in the 2012-based projections. Conversely, the populations of England and Northern Ireland are projected to be 0.9 and 0.5% higher, respectively, than previously projected.

Compared with the previous projections, the UK population at mid-2039 is higher in all broad age groups apart from those aged 75 and over, where it is 164,000 lower than the 2012-based projections.

Comparisons with the previous (2012-based) projections are given in Tables 2.5 and 2.6 and illustrated in Figure 2.5.

Table 2.5: Changes in projected births, deaths and net migration compared with the 2012-based projections, UK

	2014 to 2015		2015 to 2025		2025 to 2035		2035 to 2039	
	000s	%	000s	%	000s	%	000s	%
Births	-34	-4.2	-105	-1.3	24	0.3	6	0.2

1 . Introduction

This report provides detailed information on the principal and variant fertility assumptions used in the 2014-based national population projections. For England and for Wales, the long-term average completed family size is assumed to be 1.90 children per woman. A higher level of 2.00 is assumed for Northern Ireland and a lower level of 1.70 is assumed for Scotland. The long-term completed family size assumptions for England, Wales and Northern Ireland have seen no change from those used in the 2012-based projections, however the assumption for Scotland has been reduced from 1.75 to 1.70.

Completed Family Size is the average number of live-born children per woman which a group of women born in the same year have had by the end of their childbearing years. In general, measurement and analysis of fertility in terms of women born in a particular year is referred to as cohort fertility.

The age-specific fertility rate (ASFR) is the average number of children per woman, born to a group of women of a particular age in a particular year, normally expressed per thousand women.

The total period fertility rate (TPFR) is the average number of children per woman that would be born to a group of women if they experienced the current year's age-specific fertility rates for each year of their childbearing years. This measure is referred to as the total fertility rate, or TFR, in this Report.

2 . Principal assumptions

The numbers of births for the projections are obtained by applying the appropriate fertility rate to the number of women at each age during each year of the projection period. Because cohort fertility rates are more stable than those for calendar years (period rates), the fertility rates used in the projections are derived from assumptions relating to the year in which women were born.

The assumptions about completed family size are based on family-building patterns to date and other relevant evidence. Discussion papers showing the background information used in setting the fertility assumptions are available.

Tables 3.1 to 3.3 show average completed family size, births per 1,000 women, achieved family size, and average age at motherhood, by year of birth of woman.

Table 3.1: Completed family size for the constituent countries of the UK

The equivalent tables for the constituent countries of the UK, England and Wales, and Great Britain can be found in the data download links.

For the UK as a whole, completed family size showed a sharp decline from an average of around 2.45 children for women born in the mid-1930s to just over 2.0 for women born in the 1950s. Since then, the completed family size has declined gradually, with women born in 1968, effectively the most recent cohort to have completed their fertility, achieving an average of 1.9 children per woman.

The family sizes to be achieved by women currently in their twenties or younger are highly conjectural, but there is some evidence that suggests falls in cohort fertility could be slowing down. In particular, women born in 1980 have had more children on average by age 30 than those born in 1975 and because fertility rates at older ages are projected to remain high, the 1980 cohort is projected to have 1.98 children on average, a higher completed family size than women born in the 1970s. For women born after 1980, it has been assumed that average completed family size for the UK as a whole will fluctuate before falling and stabilising at 1.89 children for women born after 2015.

For England and for Wales, the long-term average completed family size is assumed to be 1.90 children per woman. A higher level of 2.00 is assumed for Northern Ireland and a lower level of 1.70 is assumed for Scotland. These assumptions see no change compared with the 2012-based projections for Northern Ireland, England and Wales, however, the assumption for Scotland has been reduced by 0.05.

Between 2002 and 2008, total fertility rates increased in all constituent countries of the UK, followed by a dip in 2009 (see Figure 3.1). Whilst Scotland showed a steady decline between 2009 and 2012, England, Wales and Northern Ireland showed small fluctuations in total fertility rate year on year. Between 2012 and 2013, the total fertility rate for all countries showed a large drop followed by smaller changes in 2014. For the UK, the fall was 1.92 to 1.83 between 2012 and 2013, with a rate of 1.82 in 2014. For the latest projections, it is assumed there will be a gradual upward trend in the UK fertility rate before levelling out at 1.89 in the long-term.

Over the past 10 years, fertility rates have generally been rising faster among women in their thirties and forties than for women in their twenties, so mean age at childbirth has continued to rise. The average age at motherhood for the UK as a whole is projected to increase from 28.4 years for women born in 1965 to its long-term level of 30.6 years for those born from 2015 onwards.

Figure 3.1 shows the total fertility rate (TFR) and average completed family size (CFS) for the UK between 1973 and 2039.

Figure 3.1: Total fertility rate and average completed family size, UK, 1973 to 2039

Figure 3.2 shows the assumed ultimate (long-term) age-specific fertility rates for the constituent countries of the UK.

Figure 3.2: Assumed ultimate (long-term) age-specific fertility rates, UK constituent countries

Source: Office for National Statistics

Notes:

1. All fertility data are displayed on a calendar year basis

Figure 3.3 shows the estimated and assumed average completed family size for women born between 1943 and 2009 for the constituent countries of the UK.

Figure 3.3: Estimated and assumed average completed family size, women born 1943 to 2009, UK constituent countries

Source: Office for National Statistics, National Records of Scotland, Northern Ireland Statistics and Research Agency

Notes:

1. All fertility data are displayed on a calendar year basis
2. Replacement fertility is the level of fertility required for the population to replace itself in size in the long term. In the UK, women would need to have, on average, 2.075 children to ensure long term 'natural' replacement of the population

Figure 3.4 shows the estimated and assumed total fertility rates for the constituent countries of the UK between 1973 and 2039.

Figure 3.4: Estimated and assumed total fertility rates, 1973 to 2039, UK constituent countries

3 . Assumptions for fertility variants

Table 3.4 shows the assumed long-term total fertility rates for the standard variants for the UK and its constituent countries.

Table 3.4: Assumed long-term total fertility rates for the standard variants

Country	Standard variants		
	High	Principal	Low
England	2.10	1.90	1.70
Wales	2.10	1.90	1.70
Scotland	1.90	1.70	1.50
Northern Ireland	2.20	2.00	1.80
United Kingdom	2.09	1.89	1.69

Source: Office for National Statistics

For the standard variants, fertility rates are generally assumed to move gradually from current levels to those assumed for the long-term.

Figure 3.5 shows estimated and assumed total fertility rates for the UK between 1973 and 2039 for the principal projection and high and low variants.

Figure 3.5: Estimated and assumed total fertility rates, UK, 1973 to 2039

Source: Office for National Statistics

Notes:

1. Replacement fertility is the level of fertility required for the population to replace itself in size in the long term. In the UK, women would need to have, on average, 2.075 children to ensure long term 'natural' replacement of the population
2. All fertility data are displayed on a calendar year basis

The equivalent charts for the constituent countries of the UK can be found in the relevant appendices.

Different scenarios involving both replacement fertility and constant fertility are discussed in further detail in our second release, the 2014-based extra variants report which is being published on 26 November 2015.

4. Background notes

1. Discussion papers showing the background information used in setting the fertility assumptions are available.
2. Details of the policy governing the release of new data are available by visiting www.statisticsauthority.gov.uk/assessment/code-of-practice/index.html or from the Media Relations Office email: media.relations@ons.gsi.gov.uk

These National Statistics are produced to high professional standards and released according to the arrangements approved by the UK Statistics Authority.

1 . Introduction

This report provides detailed information on the principal and variant mortality assumptions used in the 2014-based national population projections. The long-term mortality assumption for the UK projects life expectancy at birth to be 84.1 years for men and 86.9 years for women in 2039.

2 . Principal assumptions

The mortality rates for the first year of the projection, from mid-2014 to mid-2015, are based on the best estimates that could be made in the autumn of 2015 of the numbers of deaths in 2014 to 2015. Assumed improvements in mortality rates after 2014 to 2015 are based on trends in mortality rates before 2014.

The assumptions used in the 2014-based projections are that annual rates of improvement in mortality rates would converge to 1.2% for most ages in 2039 (the 25th year of the 2014-based projections) and remain constant at 1.2% a year thereafter.

However, those born after 1922 and before 1939 have exhibited greater rates of improvement over the last 25 years than those born on either side. There is currently no evidence that these differentials are declining. Similar cohort effects seen in other countries suggest that these differentials may persist well into the oldest ages. As a result, it is assumed that these cohorts will continue to experience higher rates of improvement after 2039 with the assumed rate of improvement in 2039 and beyond rising from 1.0% a year for those born in 1922 to a peak of 2.5% a year for those born in 1931 and 1932 and then declining back to 1.2% a year for those born in 1939 and later.

For those born before 1922, rates of improvement are assumed to be lower than 1.2% in 2039. Rates of improvement are assumed to decline further from 1.0% for those born in 1911 to 0.1% for those born in 1902 and earlier. These are the same assumptions for the rates of mortality improvement in the target year as those used in the 2012-based projections (where the target year was 2037).

Over the 51 year period between 1960 to 1962 and 2013 to 2014, the rates of improvement were around 1.6% per year for males and 1.4% per year for females. These rates of improvement are derived from aggregate mortality rates for ages 0 to 99 calculated using the 2011 population estimates for the UK as the standard population. The rate of improvement over the latter half of this period was higher than over the first half, particularly for males. This appears to be partly due to differential trends in smoking behaviour between males and females. Relatively higher numbers of men have now given up smoking and mortality rates for males at older ages have shown large rates of improvement in recent years.

The average annual rate of improvement over the whole of the 20th century was around 1.2% for both males and females although the improvement rates vary by age. There is considerable debate as to whether the impact of future technical, medical and environmental changes will have a greater or lesser effect on improvements in mortality in the future than they had over the 20th century.

The transition from current rates of mortality improvement by age and sex, derived from recent trends, to the assumed rates of 1.2% to 2.5% in 2039 is not assumed to take place linearly, but is assumed to converge to the proposed target rates at the same speed for males and females. There is growing evidence of generational effects for those born after 1940. Thus, in these projections, convergence to the assumed rate of improvement in 2039 has been calculated by cohort for all those born before 1960.

For those born in 1960 and later, for whom there is little evidence of generational effects, the changes in the rates of improvement to the target rate are projected by calendar year.

The rates of improvement after 2039 are assumed to remain constant (by cohort or by age, as described above) at the rate assumed in 2039 for each year thereafter. Taking account of the generally higher rates of

improvement assumed prior to 2039, this produces average annualised rates of mortality improvement of around 1.4% for males and females over the projection period to 2089 (75 years), which is the same as those experienced over the past 75 years for both males and females.

The same future rates of improvements have been assumed for all countries of the UK except for some differences (generally, slightly smaller improvements) in the period to 2039 at some ages for males and females in Scotland, as has been done in recent past projections.

In 2039, period expectation of life at birth for the UK is around 0.2 years lower than in previous projections for males and 0.6 years lower for females compared to the previous projections. These differences are mainly due to a combination of the changes in initial rates of mortality improvement and base mortality rates, the change in the target year and the assumed interpolation of the rates of improvement between 2014 and 2039. After 2039, the life expectancies for males continue to diverge from those in the 2012-based projections to around 0.6 years lower, whilst those for females fall to around 1.0 years lower.

Period expectations of life at birth and at age 65, based on the projected mortality rates, are shown for selected future years in Table 4.1. A summary of the assumed percentage rates of mortality reduction for some specimen years and ages is shown in Tables 4.2 and 4.3.

3 . Assumptions for mortality variants

Current annual improvements in mortality rates vary considerably by age and sex. For mortality, it is assumed that for most ages these improvements will gradually converge to common "target rates" of improvement, at each age and for both sexes, by the year 2039, and continue to improve at that constant rate thereafter. However, it is also assumed that those born in the years after 1922 and before 1939 (cohorts which have consistently experienced relatively high rates of mortality improvement over the last 25 years) will continue to experience higher rates of mortality improvement than the rest of the population.

The target rate assumptions are as follows:

- high variant: 2.4% annual improvement at 2039, thereafter annual improvement remaining at 2.4% for those born between 1925 and 1938 rates of annual improvement in and after 2039 will rise to a peak of 3.7% a year for those born in 1931 and 1932 and then decline back to 2.4% a year for those born in 1939 or later
- principal projection: 1.2% annual improvement at 2039, thereafter annual improvement remaining at 1.2% - for those born between 1925 and 1938 rates of annual improvement in and after 2039 will rise to a peak of 2.5% a year for those born in 1931 and 1932 and then decline back to 1.2% a year for those born in 1939 or later
- low variant: 0% annual improvement at 2039, thereafter mortality rates remaining constant - for those born between 1925 and 1938 rates of annual improvement in and after 2039 will rise to a peak of 1.3% a year for those born in 1931 and 1932 and then decline back to 0% a year for those born in 1939 or later

Table 4.4 shows period expectation of life at birth in 2039 that result from the principal and variant assumptions.

Table 4.4: Period expectation of life at birth in the year ending mid-2039 for the standard variants, UK

	High	Principal	Low
Males			
England	86.2	84.3	82.4
Wales	85.4	83.4	81.4

1 . Introduction

This report provides detailed information on the principal and variant migration assumptions used in the 2014-based national population projections. The new long-term assumption for net migration to the UK is +185,000 each year, compared with +165,000 per year in the 2012-based projections.

All 2014-based figures in this report are rounded to the nearest hundred.

2 . Migration assumptions data and methodology

Revised methodology

Following a [methodology review \(456.7 Kb Pdf\)](#) carried out by the Economic and Social Research Council Centre for Population Change in 2012, the international migration assumptions methodology was changed in the 2012-based projections. Another recommendation was the use of migration rates for certain migrant flows. In 2014, a new method for setting and applying the cross-border (intra-UK) migration assumptions as rates rather than fixed numbers of migrants was introduced and has been applied for the 2014-based projections. More detail is available on these [new methods \(399 Kb Pdf\)](#) on our website.

International migration

Assumptions of future international migration have been derived from modelling recent trends in civilian migration to and from the UK. Migrants are defined as individuals who change their country of usual residence for a period of at least a year, so that the country of destination becomes the country of usual residence.

International migration figures are derived from a number of sources. The principal source is the International Passenger Survey (IPS). Adjustments are made to account for people who enter or leave the country initially for a short stay but subsequently decide to remain for a year or more ("visitor switchers") and people who originally intend to be migrants but in reality stay in the UK or abroad for less than 1 year ("migrant switchers"). Flows to and from the Republic of Ireland, taking into account the discontinuity in 2008 due to methodological changes, are included in the IPS flows.

The IPS also excludes most, but not all, people seeking asylum. Estimates of the flows of asylum seekers (and their dependants) not captured by the IPS are obtained from Home Office data.

Cross-border migration

A new improved method for calculating cross-border migration assumptions is being implemented for the 2014-based national population projections. The assumptions for the flows between the countries of the UK are now set as rates which are based on National Health Service Central Register (NHSCR) trend data from the previous 5 years.

Annual age and sex-specific migration rates for each cross-border flow are calculated as the number of migrants at the end of the year divided by population of the country of origin at the start of the year. An average of the rates for the last 5 years of actual data (year ending mid-2010 to year ending mid-2014) is then taken and applied to the population of the country of origin at the beginning of each projection year to calculate the projected number of migrants for each flow. The main advantage of applying rates for cross-border migration is that the migrant flows are linked to the changing underlying population size and age structure. This means that the projections cannot produce implausible values, such as negative population stocks, when projected fixed levels of emigration are greater than the initial population size.

An adjustment has also been applied to the rates to take the population of the country of destination into account, ensuring that net migration levels between countries of the UK are stabilised over the course of the projection. More detail can be found in the [cross-border methodology \(399 Kb Pdf\)](#) document on our website.

Northern Ireland

From 2008, ONS migration estimates no longer use IPS data for Northern Ireland and instead use data from the Northern Ireland Statistics and Research Agency (NISRA). In order to obtain the longest possible continuous time series, Northern Ireland data back to 1992 are therefore obtained directly from NISRA.

3 . International migration assumptions

Long-term assumptions

The long-term net international migration assumptions in the 2014-based projections take effect from the year ending mid-2021.

The new long-term assumption for net international migration to the UK is +185,000 each year compared with +165,000 a year in the previous projections. This increase in net migration results from recent changes in the UK migration figures. The annual net international migration figure of +185,000 is higher than the expectations of the expert advisory panel (+153,000). The difference is due predominantly to the emigration estimate which experts on average predicted to be 383,000 per annum, compared with a proposed assumption of 333,500.

The breakdown of the long-term net international migration assumption between the 4 countries within the UK is shown in Table 5.1. This table does not include the assumptions for cross-border flows between the constituent countries of the UK since these vary over the course of the projection due to the new rates-based method being used. The cross-border flows are considered separately.

Table 5.1: Long-term annual international migration assumptions by country, year ending mid-2021 onwards, UK

	2014- based*	2012- Difference based	
International net migration			
England	170,500	150,000	20,500
Wales	4,000	3,000	1,000
Scotland	9,500	12,000	-2,500
Northern Ireland	1,000	0	1,000
United Kingdom	185,000	165,000	20,000

Source: Office for National Statistics

Notes:

1. *2014 Figures are rounded to the nearest hundred

Figure 5.1: Total international migration, UK, year ending mid-1994 to year ending mid-2025

Source: Office for National Statistics

Notes:

- 1. All migration data are displayed on a mid-year basis
- 2. Historical international migration figures for England, Scotland and Wales are primarily based on international Passenger Survey data and Northern Ireland figures are obtained directly from NISRA so aggregate totals may differ from published international migration data
- 3. 2002 to 2010 immigration and emigration figures reflect revisions made in light of the results of the 2011 Census; therefore the totals may differ from the published international migration data

Short-term assumptions

Special assumptions have been applied for the first few years of the projections (mid-2015 to mid-2020). These assumptions, shown in Table 5.2, have been formulated to represent a transition from the last year of actual data to the constant long-term assumptions. They also take into account the following factors:

- 1. further information on migration from the [Migration Statistics Quarterly Report](#), published in August 2015
- 2. a short-term armed forces flow, which has been included to account for the planned return of home armed forces personnel and their dependents from Germany

Table 5.2: Short-term annual net international migration assumptions, United Kingdom and constituent countries, year ending mid-2015 onwards

Notes:

1. International migration includes IPS flows with allowance for migrant and visitor switchers, asylum seekers and Republic of Ireland flows

Age and sex distributions

Figure 5.2 shows assumed long-term annual net international migration by age and sex for the UK from the year ending mid-2021 onwards. The international distributions are derived from an average of 5 years' unsmoothed population estimates components of change data.

Figure 5.2: Long-term annual net international migration by age and sex, United Kingdom, year ending mid-2021 onwards

Source: Office for National Statistics

4 . Cross-border migration assumptions

The assumptions for the flows between the countries of the UK are now set as rates instead of fixed numbers of migrants. Annual age and sex-specific migration rates for each cross-border flow are calculated as the number of migrants at the end of the year divided by population of the country of origin at the start of the year. An average of the rates for the last 5 years of actual data (year ending mid-2010 to year ending mid-2014) is then taken and applied to the population of the country of origin at the beginning of each projection year to calculate the projected number of migrants for each flow.

Figure 5.3 shows the trend in assumed net cross-border migration to England and how it compares with the 2012-based projections. The 2014-based assumptions show fluctuations in the earlier years but then stabilise, while the 2012-based assumptions were set as fixed numbers of migrants. The fluctuations occurring in the earlier years are due to the new method taking into account the underlying age and sex structure and population size of the countries.

The underlying annual age and sex-specific migration rates (adjusted and unadjusted) and the resulting number of migrants for each cross-border flow are available to download in the [reference tables](#).

The underlying age and sex distributions for cross-border migration are based on data from NISRA, NRS and ONS.

5 . Migration variant assumptions

The standard high and low migration variants are produced by varying the international in- and out- flow assumptions and using the principal assumptions for all other flows.

Table 5.3 shows the assumed long-term annual net migration for the standard variants for the UK and its constituent countries. In addition to that, migration variants have also been produced for Great Britain for the first time and can be found in the published reference tables.

Table 5-3: Assumed long-term annual net international migration for the standard variants, UK

	Standard variants		Special case scenario	
	High Principal	Low	Zero net migration (natural change only)	
England	233,000	170,500	108,000	0
Wales	8,500	4,000	-500	0
Scotland	18,000	9,500	1,000	0
Northern Ireland	5,500	1,000	-3,500	0
United Kingdom	265,000	185,000	105,000	0

Source: Office for National Statistics

In the standard variants, the long-term levels are assumed from the year ending mid-2021 onwards. The 2014-based projections include high and low migration variants that are "additive" for the first time. This means the UK assumptions are equal to the sum of the 4 individual countries.

In the special case scenario, the projection uses the principal assumptions for fertility and mortality and assumes that there will be zero net migration for every age for each sex. When compared to the principal projection, the zero net migration projection allows the impact of the principal net migration assumption on the projected population to be assessed.

Figure 5.7 shows estimated and assumed net international migration to the UK between year ending mid-1994 and year ending mid-2025 for the principal projection and the high and low variants.

Figure 5.7: Estimated and assumed total net international migration, United Kingdom, year ending mid-1994 to year ending mid-2025

Notes:

- 1. All migration data are displayed on a mid-year basis
- 2. Historical international migration figures for England, Scotland and Wales are primarily based on International Passenger Survey data and Northern Ireland figures are obtained directly from NISRA so aggregate totals may differ from published international migration data
- 3. 2002 to 2010 immigration and emigration figures reflect revisions made in light of the results of the 2011 Census; therefore the totals may differ from the published international migration data

The equivalent figures for the constituent countries of the UK can be found in the relevant chart section of the appendices.

6. Background notes

- 1. Discussion papers showing the [background information](#) used in setting the migration assumptions are available on our website.
- 2. Details of the policy governing the release of new data are available by visiting www.statisticsauthority.gov.uk/assessment/code-of-practice/index.html or from the Media Relations Office email: media.relations@ons.gsi.gov.uk

These National Statistics are produced to high professional standards and released according to the arrangements approved by the UK Statistics Authority.

1 . Introduction

This report answers some of the questions users most frequently ask on national population projections in general as well as the 2014-based release more specifically.

2 . General national population projections FAQs

What are the national population projections?

National population projections are prepared by the Office for National Statistics (ONS) on behalf of the National Statistician and the Registrars General for Scotland and Northern Ireland. They are produced every 2 years and provide projections of the future size and age structure of the population for the UK and its constituent countries. The national population projections are National Statistics, which means that they undergo regular quality assurance reviews and are produced free from political interference.

How are the projections produced?

The national population projections are based on the latest available mid-year population estimate and a set of demographic assumptions about future fertility, mortality and migration based on analysis of trends and expert advice. They are produced using the internationally accepted cohort component methodology. This method accounts for changes which increase or decrease the population (births, deaths and net migration) and models the effect of these changes and the passage of time on the age structure of the population.

Do the projections take government policies into account?

The national population projections are not forecasts and do not attempt to predict the impact that future government policies, changing economic circumstances or other factors (whether in the UK or overseas) might have on demographic behaviour. They simply provide the population levels and age structure that would result if the underlying assumptions about future fertility, mortality and migration were to be realised.

What population is covered by the projections?

Projections are made of the usually resident population of the UK and its constituent countries, whatever their nationality. The usually resident population includes all long-term international migrants (people changing their country of usual residence for at least one year). However, the usually resident population does not include short-term migrants who come to or leave the UK for less than a year.

How are the assumptions underlying the projections agreed?

The assumptions about future levels of fertility, mortality and net migration are agreed in liaison with the devolved administrations (namely National Records of Scotland (NRS), the Northern Ireland Statistics and Research Agency (NISRA) and the Statistical Directorate of the Welsh Government (WG)), following consultation with main users of projections in each country and advice from an expert academic advisory panel. Details of the [membership of the panel and minutes of the meeting](#) are published on our website.

Why are the national population projections produced?

The main purpose of the national population projections is to provide an estimate of the future population of the UK (and its constituent countries) as a common framework for use in national planning in a number of different fields.

Who are the main users of the projections, and what are they used for?

The national population projections are widely used across government for planning purposes. Examples include:

- the Office for Budget Responsibility use the projections as a main input to their long-term fiscal projections published in the fiscal sustainability report
- the Department for Work and Pensions use the projections extensively to produce forecasts of expenditure for benefits and pensions and as a main input for analysis on policy areas such as extending working lives
- the Department for Education use the projections as the basis for their projections of future school pupil numbers

The national population projections also provide the base for other products such as subnational population projections and household projections, which are widely used for resource allocation and planning.

Why do you produce variant projections?

Projections are uncertain and becoming increasingly so the further they are carried forward in time. Users of population projections should take account of this uncertainty in any decisions they base on the projections. To help with this, the principal (main or central) projection is accompanied by some variant projections, which are based on alternative, but still plausible, assumptions. These variant projections provide an indication of uncertainty by allowing users to consider the impact upon the population if future fertility, mortality and migration differ from the assumptions made for the principal projection. The publication of variant projections is an internationally recognised method for illustrating the uncertainty associated with population projections.

Also produced are a number of special scenario variants that allow users to consider "what ifs". So for example the "No mortality improvement" variant, due to be published in November 2015, shows what the population would look like if mortality rates stayed at similar levels to those currently observed. Some allow decomposition of the projections for example the "Zero net migration (natural change only)" variant looks at what would happen if net migration was zero at every age, by comparing this to the principal projection the impact of the migration assumptions can be assessed.

What is the "central" or principal projection and how is it different from the variant projections?

The principal population projection is produced using a set of assumptions of future levels of fertility, mortality and migration. These assumptions are set using past trend data and advice from an expert panel. Projections are inherently uncertain and becoming increasingly so the further they are carried forward in time. To help users with this, the principal (main or central) projection is accompanied by some variant projections, which are based on alternative, but still plausible, assumptions. These variant projections provide an indication of uncertainty by allowing users to consider the impact upon the population if future fertility, mortality and migration differ from the assumptions made for the principal projection. The publication of variant projections is an internationally recognised method for illustrating the uncertainty associated with population projections.

How far ahead do the projections go?

Projections are uncertain and become increasingly so the further they are carried forward in time. For this reason, analysis of the projection results mainly focuses upon the first 10 or 25 years of the projection period, which corresponds with the planning horizons of the majority of users of the projections, whilst recognising that uncertainty will be greater over a 25 year period.

However, some main users require projections over a longer period for modelling purposes, and the principal projection is also published for up to 100 years ahead. However, caution should be used when interpreting this longer-term projection as projections become increasingly uncertain the further into the future they go.

Do you produce population projections by religion or ethnicity?

We do not produce population projections by religion or ethnicity. We publish national population projections by age and sex for the UK and its constituent countries. We also produce subnational population projections for England by age and sex which are published about 7 months after the national population projections.

3 . 2014-based national population projections FAQs

What is the latest set of national population projections?

The latest set of national population projections is the 2014-based projections that we published on 29 October 2015. They are based on the estimated population at 30 June 2014. The principal (central) projection is based on assumptions considered to best reflect demographic patterns at the time they were adopted. We also produce a number of variant population projections, based on alternative, but still plausible, assumptions of future fertility, mortality and migration. Some special case scenario projections are also published. Nine variant projections are published alongside the principal projections on 29 October 2015, and a further 7 variant projections will be published on 26 November 2015.

Where can I find the latest projections?

The [latest national population projections](#) are available from our website. Detailed information on the assumptions underlying the projections and the methodology used to produce the projections can be found in the published reports. Information on 7 further variants will be published on 26 November 2015, and the reference volume in spring 2016. There are a number of interactive tools and supporting documents to help users view and understand the projections.

What data have been published?

For the 2014-based projections, principal projections data have been published up to 100 years ahead for the UK, Great Britain, England and Wales and each of the constituent countries.

Variant projections have been published up to 25 years ahead for the UK and each of the constituent countries. The low migration, high migration and zero net migration (natural change only) variants have also been published for Great Britain on 29 October 2015 and further variants are available from 26 November 2015.

Data for each country or variant combination have been published in 2 summary tables and 1 zipped open data file.

Summary table 1 contains the total projected population for all years of the projections, the components of change and other summary statistics.

Summary table 2 contains the projected population in 5 year age groups for all years of the projection.

The XML open data files contain:

- population by single year of age (0 to 104), age groups (105 to 109, 110 and over) and sex
- fertility assumptions by single year of age (15 to 46)
- mortality assumptions by single year of age (0 to 125) and sex
- cross border rates for each country flow by single year of age (0 to 125) and sex
- births by age of mother (15 to 46)
- deaths by age (0 to 105) and sex
- in, out and net cross border migration by age (0 to 105) and sex
- in, out and net international migration by age (0 to 105) and sex
- in, out and net total migration by single year of age (0 to 105) and sex

How do I find the table I want without the interactive table download tool?

The projections have been categorised by country and by type of information and these groupings can be accessed through links on the left hand side of the reference table webpage.

If you have any difficulty finding the information you require please contact the projections team at projections@ons.gsi.gov.uk, Tel: +44 (0)1329 444652.

What are the findings of the 2014-based projections?

A commentary on the findings of the projections, along with files containing the detailed results, are available on the [release page](#). Main points are:

- the UK population is projected to increase by 9.7 million over the next 25 years from an estimated 64.6 million in mid-2014 to 74.3 million in mid-2039
- the UK population is projected to reach 70 million by mid-2027
- assumed net migration accounts for 51% of the projected increase over the next 25 years, with natural increase (more births than deaths) accounting for the remaining 49% of growth
- over the 10 year period to mid-2024, the UK population is projected to increase by 4.4 million to 69.0 million. This is 249,000 higher than the previous (2012-based) projection for that year
- the population is projected to continue ageing with the average (median) age rising from 40.0 years in 2014 to 40.9 years in mid-2024 and 42.9 by mid-2039
- by mid-2039 more than 1 in 12 of the population is projected to be aged 80 or over

What are the assumptions underlying the latest projections?

We produce a principal (central) projection and also a number of variant projections based on alternative assumptions. The 2014-based principal population projection for the UK assumes:

- a long-term average completed family size of 1.89 children per woman
- life expectancy at birth in 2039 of 84.1 years for men and 86.9 years for women, with constant rates of mortality improvement assumed thereafter
- a long-term assumption of annual net migration to the UK of +185,000 per year

The long-term assumptions above are complemented by short-term assumptions designed to allow a realistic convergence to the long-term assumption. For example, assumed net migration for the first 7 years of the projection is higher than the long-term assumption above. Detailed information on the [assumptions underlying the projections](#) can be found on the release page.

Is the projected growth in the population due to births or migration?

Projected growth over the next 25 years is evenly split between the direct effect of these two factors. Of the 9.7 million projected increase in the population over the full projection period to mid-2039, 4.7 million (49%) is due to projected natural increase and 5.0 million (51%) is due to assumed net migration.

Past international migration also has an indirect impact on the population through its effect on the numbers of births and deaths – for example, women who were born overseas but who give birth after migrating to the UK will increase the numbers of births, while the numbers will be decreased by women born in the UK who migrate overseas before giving birth (assumptions of future fertility and mortality are based on past trends of all residents irrespective of where they were born).

Because migration is concentrated at young adult ages, the assumed level of future net migration has a much greater effect on the projected number of women of childbearing age and hence the projected number of births, than on projected number of deaths over the 25 year period of the projection. Of the 4.7 million natural increase projected between mid-2014 and mid-2039, only 3.1 million would occur if net migration were zero (at each and every age) throughout the projection period. Thus about 68% of the projected increase in the population over the period mid-2014 to mid-2039 is either directly attributable to future migration (51% of projected growth), or indirectly attributable to future migration through its effect on births and deaths (17 per cent of projected growth).

Care should be taken in interpreting these figures as "the indirect impact of migration". A fuller assessment of this would consider:

- births to, and deaths of, people who had migrated to the UK before 2014
- how to account for births to, and deaths of, UK-born people who had emigrated and subsequently returned to the UK
- how to account for births to, and deaths of, UK-born people who had parents (or grandparents etc) who were themselves immigrants, and the corresponding figures for foreign-born people descended from UK emigrants

Do the assumptions about future migration reflect the latest patterns of international migration?

The 2014-based principal projection assumes that levels of net migration to the UK will be +185,000 per year from 2020 2021 onwards. Net migration rose between 2012 and the release of these projections. The [August 2015 Migration Statistics Quarterly Report](#) showed net migration estimated as 330,000 to the year ending March 2015, a statistically significant increase from 236,000 for the year ending March 2014 and was the highest estimated net migration on record at that point. Therefore the assumptions for the years to 2020 2021 are higher than the long-term assumption but are assumed to converge from the levels seen between 2013 and early 2015 to the long-term assumption.

The long-term assumptions have been set based on migration data to mid-2014. An allowance has been made in the short-term for the planned return of armed forces to the UK. The provisional estimates of migration to March 2015 have also been taken into account in the assumed migration for the first year of the projection.

What changes have been made to the methodology?

The methods for setting and implementing the cross-border (intra-UK) migration have been changed. More information on this follows.

The UK, GB and England and Wales projections have been calculated as the sum of the projections for the 4 individual countries (England, Wales, Scotland and Northern Ireland). Therefore, the projected population numbers, deaths at each age and births at each age of mother for the UK are just the sum of those for the 4 individual countries. The "assumed" UK fertility and mortality rates are then "back-calculated" from these projected births, deaths and population numbers.

Previously some of the UK variant projections were "non-additive", that is, they were not calculated as the sum of those for the 4 individual countries. This change has been introduced partly as a result of the introduction of a new cross-border migration methodology and partly to meet a user requirement for variant projections for Great Britain.

Have you changed the methods for setting migration assumptions?

In 2012, we commissioned the Economic and Social Research Council Centre for Population Change to carry out a review of the methodology used in setting migration assumptions for the NPPs and to make recommendations for future methods.

As a result, the methodology for setting the migration assumptions for the 2012-based NPPs were revised to incorporate findings from the review.

No further changes have been made for the 2014-based projections international migration assumptions. However, changes have been made to the methods for setting the cross-border (intra-UK) assumptions.

Why have you changed the methods for setting cross-border migration assumptions?

Introducing migration rates into the projections is a continuation of the work to implement the recommendations from the ESRC review and is another step towards fully aligning our projections with the most up to date academic ideas.

The [ESRC review](#) set out the main benefits of using migration rates rather than fixed numbers of migrants. The main advantage is that the process is clearly related to the population at risk, allowing the migrant flows to

change on the basis of the underlying population size and age structure. This means that the projections cannot produce implausible values, such as negative population stocks, when projected fixed levels of emigration are greater than the initial population size.

This is a particular issue for Northern Ireland where there is a high level of cross border migration of 18 to 19 year olds out of Northern Ireland but an often decreasing projected population in this age group. If fixed migrant numbers are assumed on the basis of past trends regardless of the underlying population size, this can lead to the migration rate of 18 to 19 year olds out of Northern Ireland increasing over the course of the projection. This issue has previously required a specific ad hoc adjustment, but the use of rates resolves the issue.

What is the new method used to set the migration assumptions?

The cross-border (intra-UK moves) migration assumption is set as a rate for the first time in the 2014-based projections. This means the projections assume a constant proportion of the population at each age will move from one country of the UK to another. Since the population at each age changes each year, the number of people moving across borders within the UK will also change through the projection period. However the cross-border flows of people do stabilise during the projection period.

More information on the [cross-border assumptions](#) can be found within the release.

Details of the [new method were \(399 Kb Pdf\)](#) published in June 2015.

Where do all the projected migrants, go to and, come from?

Our migration assumptions are not created based on where people are migrating to, or from, and they do not provide forecasts or projections of movements of people from particular countries to and from the UK.

We do publish [estimates of long-term international migration](#) that provides information on where people migrate to, or from.

What do the latest projections show regarding population ageing?

The population is projected to rise most quickly for the oldest age groups. The number of people aged 80 to 89 is projected to nearly double from 2.5 million to 4.6 million over the 25 years to mid-2039. The number of people aged 90 and over is projected to nearly treble, from 0.6 million in mid-2014 to 1.7 million in mid-2039. The increases in State Pension Age mean that the ratio of working age people to each person of state pensionable age is projected to increase slightly from 3.22 in mid-2014 to 3.32 in mid-2024 and then to decline to 2.71 in 2039.

How do the 2014-based projections compare with previous projections?

In the short-term the projected future population size is slightly higher than that in the previous (2012-based) projections. This is partly attributable to the base 2014 population being 86,000 higher in the 2014-based projection than in the 2012-based projections. Population growth is projected to be lower in the 2014-based projections than the 2012-based, and therefore in the long-term the 2014-based projections are lower. The lower growth reflects changes in the age structure of the base population (which affects the numbers of projected births and deaths) and changes in assumptions made in the 2014-based projections.

The principal long-term fertility assumption in the 2014-based projections remains unchanged from the 2012-based projections at 1.89 children per woman; in the short-term levels of fertility are assumed to be lower than in the 2012-based projections. More information on the [changes to the fertility assumptions](#) can be found on our website.

In general the [annual rates of mortality improvement in the longer-term have remained the same as in the 2012-based projections](#). More information on [mortality](#) can be found on our website.

The [2014-based long-term assumption for net migration to the UK](#) is higher at +185,000 each year, compared with +165,000 each year in the 2012-based projections. These changes reflect the most recent trends in international migration. More information on [migration](#) can be found on our website.

The mortality assumptions have not changed so why are you projecting lower life expectancy?

The mortality assumptions are set in terms of rates of improvement of mortality rates by age, sex and year. The long-term rates of improvement (i.e. those in the 25th year of the projection period (2039) and thereafter) are the same as those assumed in the previous 2012-based projections. However, we have assumed higher mortality rates at nearly all ages and lower rates of mortality improvement at most ages over 65 in 2014 compared to those projected for 2014 in the 2012-based projections. The combination of these factors, for both males and females, gives rise to projected period life expectancies that are lower than those in the 2012-based projections. Life expectancy figures for 2014 and 2015 also reflect an adjustment made to allow for the much larger number of deaths registered in early 2015 compared to those projected.

How accurate have past projections been?

We published an analysis of the past [accuracy of national population \(1.03 Mb Pdf\)](#) projections in July 2015. This analysis considered the 1955-based to 2012-based projections and compared these projections with the latest estimates of the UK population up to 2013, where available. The analysis found that the mean absolute error of the projected total UK population 20 years ahead was about 2.7% overall (when considering 1955-based to 2012-based projections). This would correspond to around 2.0 million people (2.7% mean absolute error calculated on the 2014-based principal projection for 2034). The largest differences between projected and actual populations were found to be for the youngest and oldest ages.

What are the confidence intervals or error margins around the projections?

We do not publish confidence intervals around the projections. The projections are inherently uncertain and become more so the further they are carried forward in time, particularly for smaller geographical areas. Variant projections are produced to provide an indication of uncertainty by allowing users to consider the impact upon the population if future fertility, mortality and migration differ from the assumptions made for the principal projection.

When is the UK population projected to reach 70 million, and why is this population level of significance?

According to the 2014-based principal projection, the UK population will reach 70 million by mid-2027, in the same year as projected by the 2012-based and the 2010-based projections. In comparison, the 2008-based projections indicated that it would reach this level in early 2029, and the 2006-based projections in early 2028.

A population level of 70 million is of no special demographic significance, although some customers of population statistics will inevitably be interested in when and how fast the population might reach numerical milestones such as 50 million, 60 million and 70 million. The UK population is estimated to have reached 50 million in 1948 and 60 million by mid-2005. It is projected that the population will rise from 60 to 70 million over a period of 22 years, compared to the 57 years over which it rose from 50 to 60 million.

Will the UK population go on growing forever?

Under the principal projection assumptions, the size of the UK population is projected to continue increasing over the projection period. However projections are uncertain and become increasingly so the further they are carried forward.

When will all the variant projections be available?

The release on 29 October 2015 covered the main (principal) 2014-based projections and 9 main variant projections based on alternative assumptions. On 26 November 2015, we will release a further 7 variant projections that illustrate additional alternative scenarios to supplement the projections released in October. This November release will form part of the overall release of the 2014-based national population projections, the main results of which are described in the statistical bulletin and supplementary reports published on 29 October.

Are projections for areas within the UK available?

The 2014-based national population projection release includes projections for the UK, Great Britain, England and Wales, England, Wales, Scotland and Northern Ireland. Our projections for subnational areas for England are planned for publication in May/June 2016. Subnational projections for areas in Wales, Scotland and Northern Ireland are produced by the Welsh Government, National Records for Scotland (NRS) and Northern Ireland Statistics and Research Agency (NISRA) respectively.

How do future changes to the UK population compare with other countries in Europe?

There are differences between our projections methodology and that used by Eurostat. For example, our projections are based on the population estimates at 30 June while the Eurostat projections are based on an estimate of the population at 1 January. Eurostat also make different assumptions about future levels of fertility, mortality and migration.

The latest Eurostat projections are [EUROPOP2013](#).

The estimated population in the base year for our projections is 0.4 million higher than the Eurostat projected population. By 2024, we project the population to be approximately 0.8 million higher than that projected by Eurostat and this difference of 0.8 million remains in 2039.

According to the Eurostat figures, the estimated resident population of the UK at 1 January 2014 was 64.2 million, with only Germany and France estimated to have more people. The UK is projected to have more people than France by 2030 and is projected to have the largest population in the EU by 2047.

The population of the EU28 as a whole is projected to increase by 2% over the 10 years to 2024 and by 3% in the 25 year period to 2039. Of the member states, the UK is projected to be the fourth fastest growing population, with only Luxembourg, Belgium and Sweden projected to grow at a faster rate.

4. Background notes

1. Details of the policy governing the release of new data are available by visiting www.statisticsauthority.gov.uk/assessment/code-of-practice/index.html or from the Media Relations Office email: media.relations@ons.gsi.gov.uk

These National Statistics are produced to high professional standards and released according to the arrangements approved by the UK Statistics Authority.
